Background

Patterned ground features are typical components of arctic Siberian wetlands underlain by permafrost. Ice-wedge polygons often accommodate small and shallow periglacial surface waters. They provide suitable habitats for freshwater ostracods (Crustacea, Ostracoda). Ostracods are sensitive to environmental conditions, and have been widely used as biological indicators for past and present environmental changes in temperate regions.

Within the frame of the joint German-Russian DFG-RFBR project “Polygons in tundra wetlands: state and dynamics under climate variability in Polar Regions (POLYGON)” field studies of recent polygon dynamics were carried out in the Indigirka Lowland in 2011 (Fig. 1) to investigate the lacustrine and ecotrophic classes of otracod assemblages and habitat conditions.

Study site and method

The study sites were located in the flood plain and the adjacent thermokarst affected lowland along the Bereisky River near the VVTV-relation Poly (70°32’12.1’’N, 147°46’29.9’’E, 11 m asl, Fig. 2). 27 periglacial water bodies located in different landscape units were studied (Figs. 3; 4). We caught 100 living ostracods per site, and sampled the pond water, pond substrates as well as precipitation for sedimentological, hydrochemical and stable water isotope analysis. Ostracod and environmental data were combined in a multivariate-statistical approach (from-metric multidimensional scaling, NMDS).

We focused on the seasonal variability of a selected interpolygon pond site (KYT-01) and its ostracod population in 4-day intervals. A monitoring program was carried out to measure changes in air and water temperatures as well as water conductivity and water level fluctuations between 20 July and 26 August, 2011.

Pond substrate and hydrochemistry

The pond substrate consisted of unconsolidated fine grained, organic-rich material. All sites located in the river flood plain the lower amounts of TOC (11 – 26 wt %) were found while substrate from ponds in other landscape units contained considerably higher TOC (28 – 50 wt %). TOC in interpolygon ponds was < 25 wt % while substrate from interpolygon ponds ranged from 33 – 44 wt % TOC.

Polygons ponds displayed little variability of acidity (0.4 mmol l\(^{-1}\)) and alkalinity (0.2 – 1.6 mmol l\(^{-1}\)). Well-oxygenated (\(O_2: 5.4 - 11.8 \text{ mg l}^{-1}\)) and dilute ponds (EC: 19 – 53 \(\mu\text{S cm}^{-1}\)) with slightly acidic pH (5.5 – 7.1) hosted an abundant and diverse ostracod fauna.

Ostracod record

A total of 4449 identified ostracods from 8 species and 3 taxa represent the first record of the ostracod fauna in the Indigirka Lowland (Figs. 5; 6). Species assemblages in the studied waters were clearly dominated by Fabaeformiscandona pedata and juvenile Candona spinifera. Fabaeformiscandona spinifera, Fabaeformiscandona granulatae Fabaeformiscandona sp. 1 and Fabaeformiscandona sp. II were documented for the first time in continental Siberia.

The NMDS (Fig. 7) reflects a rather homogeneous ostracod species distribution. species that occur preferentially in certain pond substrate properties,

Monitoring of an ostracod assemblage

Monitoring site KYT-01 (Fig. 8) accommodates an 11.5 x 13.5 m wide interpolygon pond. A boggy moss-zeewedge, polygon walls, and frost cracks completely enclosed the pond. The thaw depth below the pond centre was 40 – 58 cm while it was 19 – 24 cm at the pond rim.

Repeated sampling of a low-center polygon pond revealed detailed insights in the population dynamics of F. pedata (Fig. 9). During 40 days, in total 989 ostracods were caught in pond KYT-01. The proportion of adult male specimens declined from 98 % to 22 % when they were growing to adulthood. Adult male specimens were present early and their numbers remained stable at a low level (11 – 15 %). In contrast, adult female specimens appeared from early August on and reached high numbers (up to 60 %). Thus, at the end of the 2011 summer the ostracod assemblage in the monitored pond was not only dominated by F. pedata, but also by adult female specimens.

Stable water isotope record of different water types in the Indigirka study area relative to the VSMOW.

Monitoring

Recorded air and water temperatures (Fig. 11a) fluctuated daily by about 10°C and a cooling trend was superimposed on these records towards the end of the monitored time period in autumn 2011.

Variations in dissolved ion content accompanied temperature fluctuations throughout the water column (Fig. 11b, c). The mean water depth was 35 cm but water level fluctuations of 8 cm occurred during precipitation events.

Hydrochemical data from 10 monitoring events revealed stable pH values (Fig. 11d). The amount of dissolved oxygen as well as the DIC content increased towards the end of the monitoring period when air and water temperatures decreased.

The stable water isotope record (Fig. 10) suggests a saline water source for the ponds that underwent evaporation.

Air temperature and precipitation were identified as the main drivers of water temperature, ion concentration, stable water isotope composition, and water level in polygon ponds.
