Introduction

The EU-funded project SANGOMA – Stochastic Assimilation of the Next Generation Ocean Model Applications – provides new developments in data assimilation to ensure that future operational systems can make use of state-of-the-art data-assimilation methods and related analysis tools. One task of SANGOMA is to develop a library of shared tools for data assimilation with a uniform interface so that the tools are easily usable from different data assimilation systems.

DIAGNOSTIC TOOLS

The diagnostic tools provide functionality to analyze the performance of an ensemble assimilation system. Available tools include:

- **sangoma_ComputeHistogram**
  Compute ensemble rank histograms (Fig. 1)

- **sangoma_ComputeEnsStats**
  Compute higher-order ensemble statistics (Fig. 2)

- **sangoma_ComputeCRPS**
  Compute continuous ranked probability score (CRPS) and decompose it into reliability and resolution (Fig. 4)

- **sangoma_ComputeSensitivity**
  Compute sensitivity of a posterior mean to observations in a particle filter

- **sangoma_ComputeMutualinformation**
  Compute mutual information in a particle filter

- **sangoma_RelativeEntropy**
  Compute relative entropy in a particle filter

- **sangoma_ArM**
  Calculate array modes and associated quantities to assess the performance of an observational array

**Fig. 1:** Example of an ensemble rank histogram used to access the ensemble quality. The rank histogram information is computed using the tool `sangoma_ComputeHistogram`.

**Fig. 2:** Example of ensemble skewness and kurtosis (3rd and 4th moment of the ensemble statistics) for three different filter configurations. The moments are computed using `sangoma_ComputeEnsStats`.

**Fig. 3:** Example of a HF-Radar setup in the Ligurian Sea. `hfradar_extractf` provides an observation operator for HF radar surface currents.

**Fig. 4:** Application example for `sangoma_ComputeCRPS`: Reliability (bottom) and resolution (top) components of the CRPS for the SSH from an example of assimilating satellite altimetry. The assimilation improves both components.

**Fig. 5:** Example of the realization of a random field constrained by the advection field. Such random fields can be computed using the tool for weakly constrained ensemble perturbations.

**Fig. 6:** Example of Gaussian anamorphosis. The sea-ice concentration exhibits a non-Gaussian distribution, which can be transformed into a Gaussian using the tool for empirical Gaussian anamorphosis.

UTILITY TOOLS

The utility tools provide additional functionalities for data assimilation systems like:

- **sangoma_ComputePOD**
  Compute dominant modes of proper orthogonal decomposition from ensemble of snapshots

- **sangoma_Costgrad**
  Compute costs of values of an objective function and its gradient using POD information

- **hfradar_extractf**
  Observation operator for HF radar surface currents (Fig. 3)

**ANALYSIS STEPS**

Typically, the different tool boxes for data assimilation already include analysis steps. However, the SANGOMA tools also provide a set of ensemble-based Kalman filters.

SANGOMA tools

For the SANGOMA tools we consider 5 categories, which are described below. The tools are implemented in Fortran and as scripts for Matlab or Octave. The project deliverables, which are available on the project website, provide an extensive documentation of the tools. The tools and application examples can be downloaded at

Your Feedback: Survey on Tools

The project members are working to implement further tools for a code release in fall 2015. We would like to hear your feedback on which tools are useful for you, especially for the diagnostic tools. Please complete our survey about your interest in tools at

Survey: http://www.data-assimilation.net

Buttion tools

The perturbation tools provide functions to generate perturbations with prescribed properties. They can be used to generate ensembles of model states or to perform perturbed ensemble integrations. Available are:

- **sangoma_EOFCovar**
  Initialize a covariance matrix from decomposition of an ensemble into empirical orthogonal functions (EOFs)

- **sangoma_MVNormalize**
  Compute a multivariate normalisation of a state vector

- **sangoma_pseudornd2D**
  Generate random fields with given correlation length from transformation into frequency space

- **Weakly Constrained Ensemble Perturbations**
  Generate ensemble perturbations satisfying a linear constraint (Fig. 5)

**Fig. 6:** Example of Gaussian anamorphosis. The sea-ice concentration exhibits a non-Gaussian distribution, which can be transformed into a Gaussian using the tool for empirical Gaussian anamorphosis.

PERTURBATION TOOLS

**Transformation tools**

Assimilation algorithms that base on the Kalman filter assume Gaussian distributions for optimality. The tools provide functionality to perform transformations that improve the performance with non-Gaussian distributions:

- **Empirical Gaussian Anamorphosis**
  Determine the empirical transformation function to transform the distribution of a variable into a Gaussian distribution and perform the transformation (Fig. 6)

- **Observation operator for HF radar surface currents**
  The perturbation tools provide functions to generate perturbations with prescribed properties. They can be used to generate ensembles of model states or to perform perturbed ensemble integrations. Available are:

- **sangoma_EOFCovar**
  Initialize a covariance matrix from decomposition of an ensemble into empirical orthogonal functions (EOFs)

- **sangoma_MVNormalize**
  Compute a multivariate normalisation of a state vector

- **sangoma_pseudornd2D**
  Generate random fields with given correlation length from transformation into frequency space

**Weakly Constrained Ensemble Perturbations**

Generate ensemble perturbations satisfying a linear constraint (Fig. 5)
