for Marine Microbiology**

Are benthic
remineralsation rates
in the **Arctic deep sea** influenced by
decreasing sea-ice coverage and
increasing primary production?

How?

Hypothesis

Arrigo et al., Geophysical Research Letters, Vol. 35, 2008

Boetius et al., Science, Vol. 339, 2013

Decreasing sea-ice coverage
Increasing primary production

Increasing benthic
rem mineralisation rates

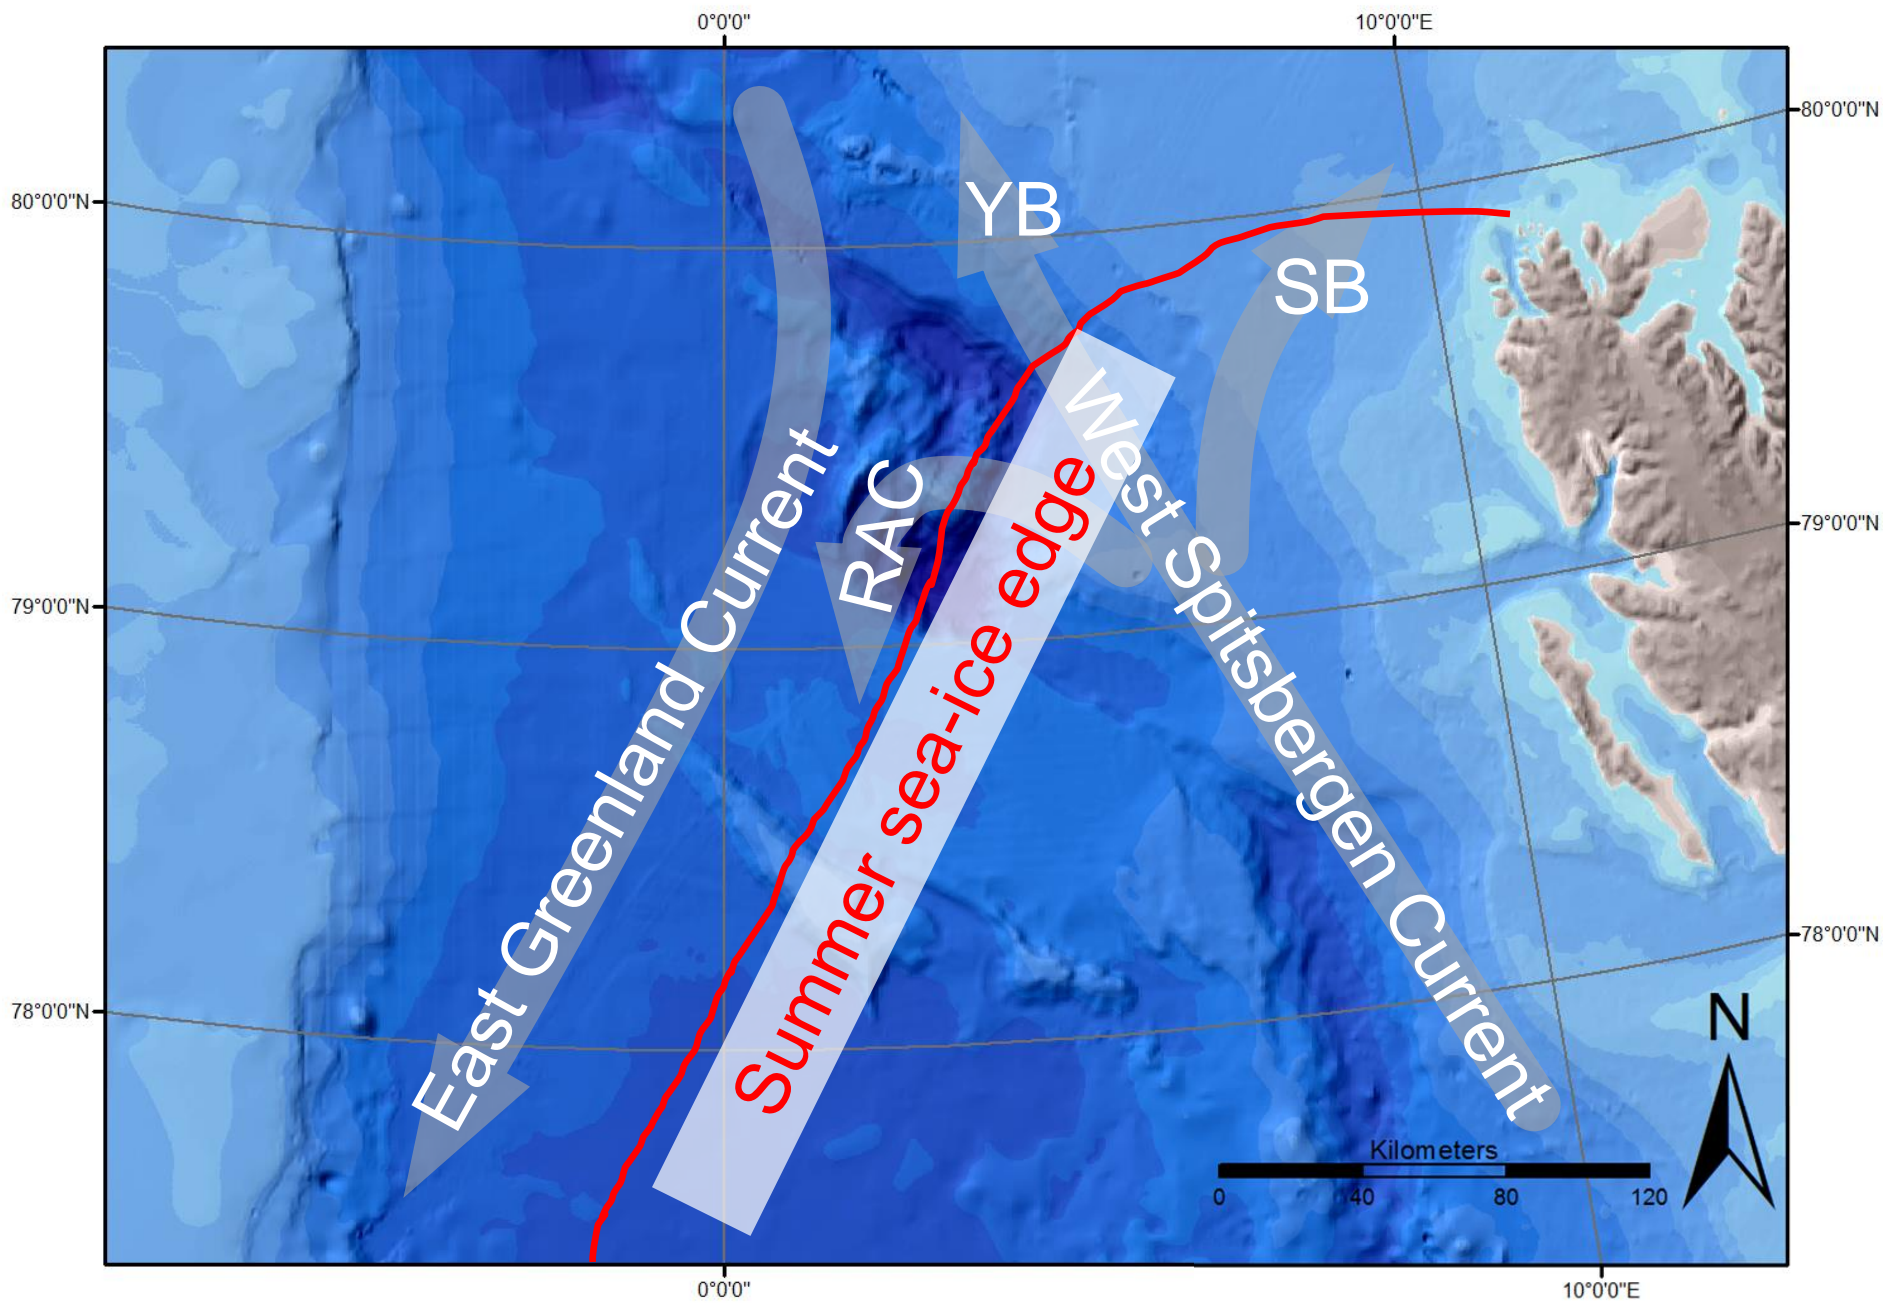

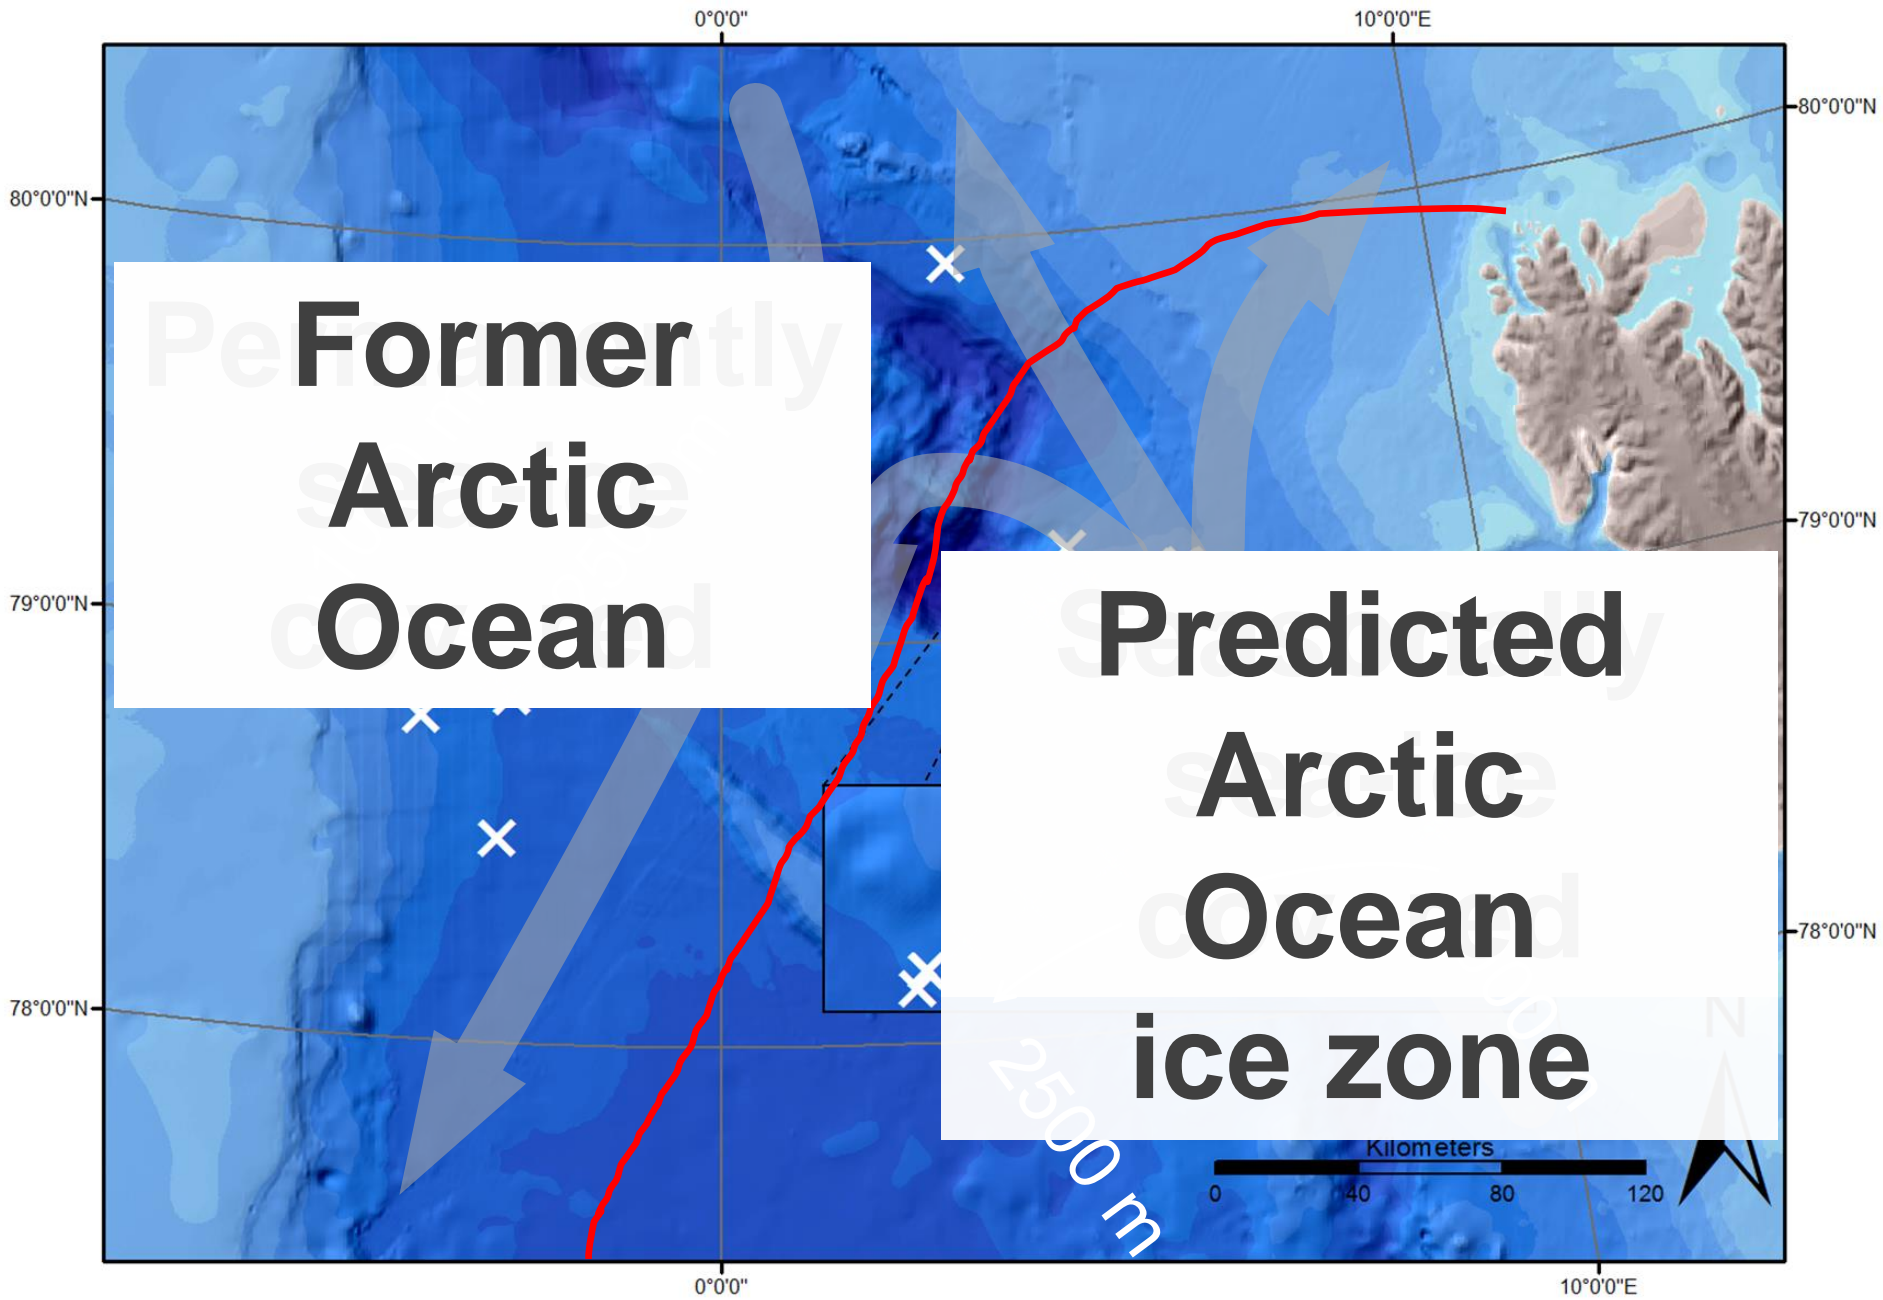

Greenland

Fram
Strait

nds
)

Oxygen fluxes: ex situ & in situ

Diffusive oxygen uptake (DOU)

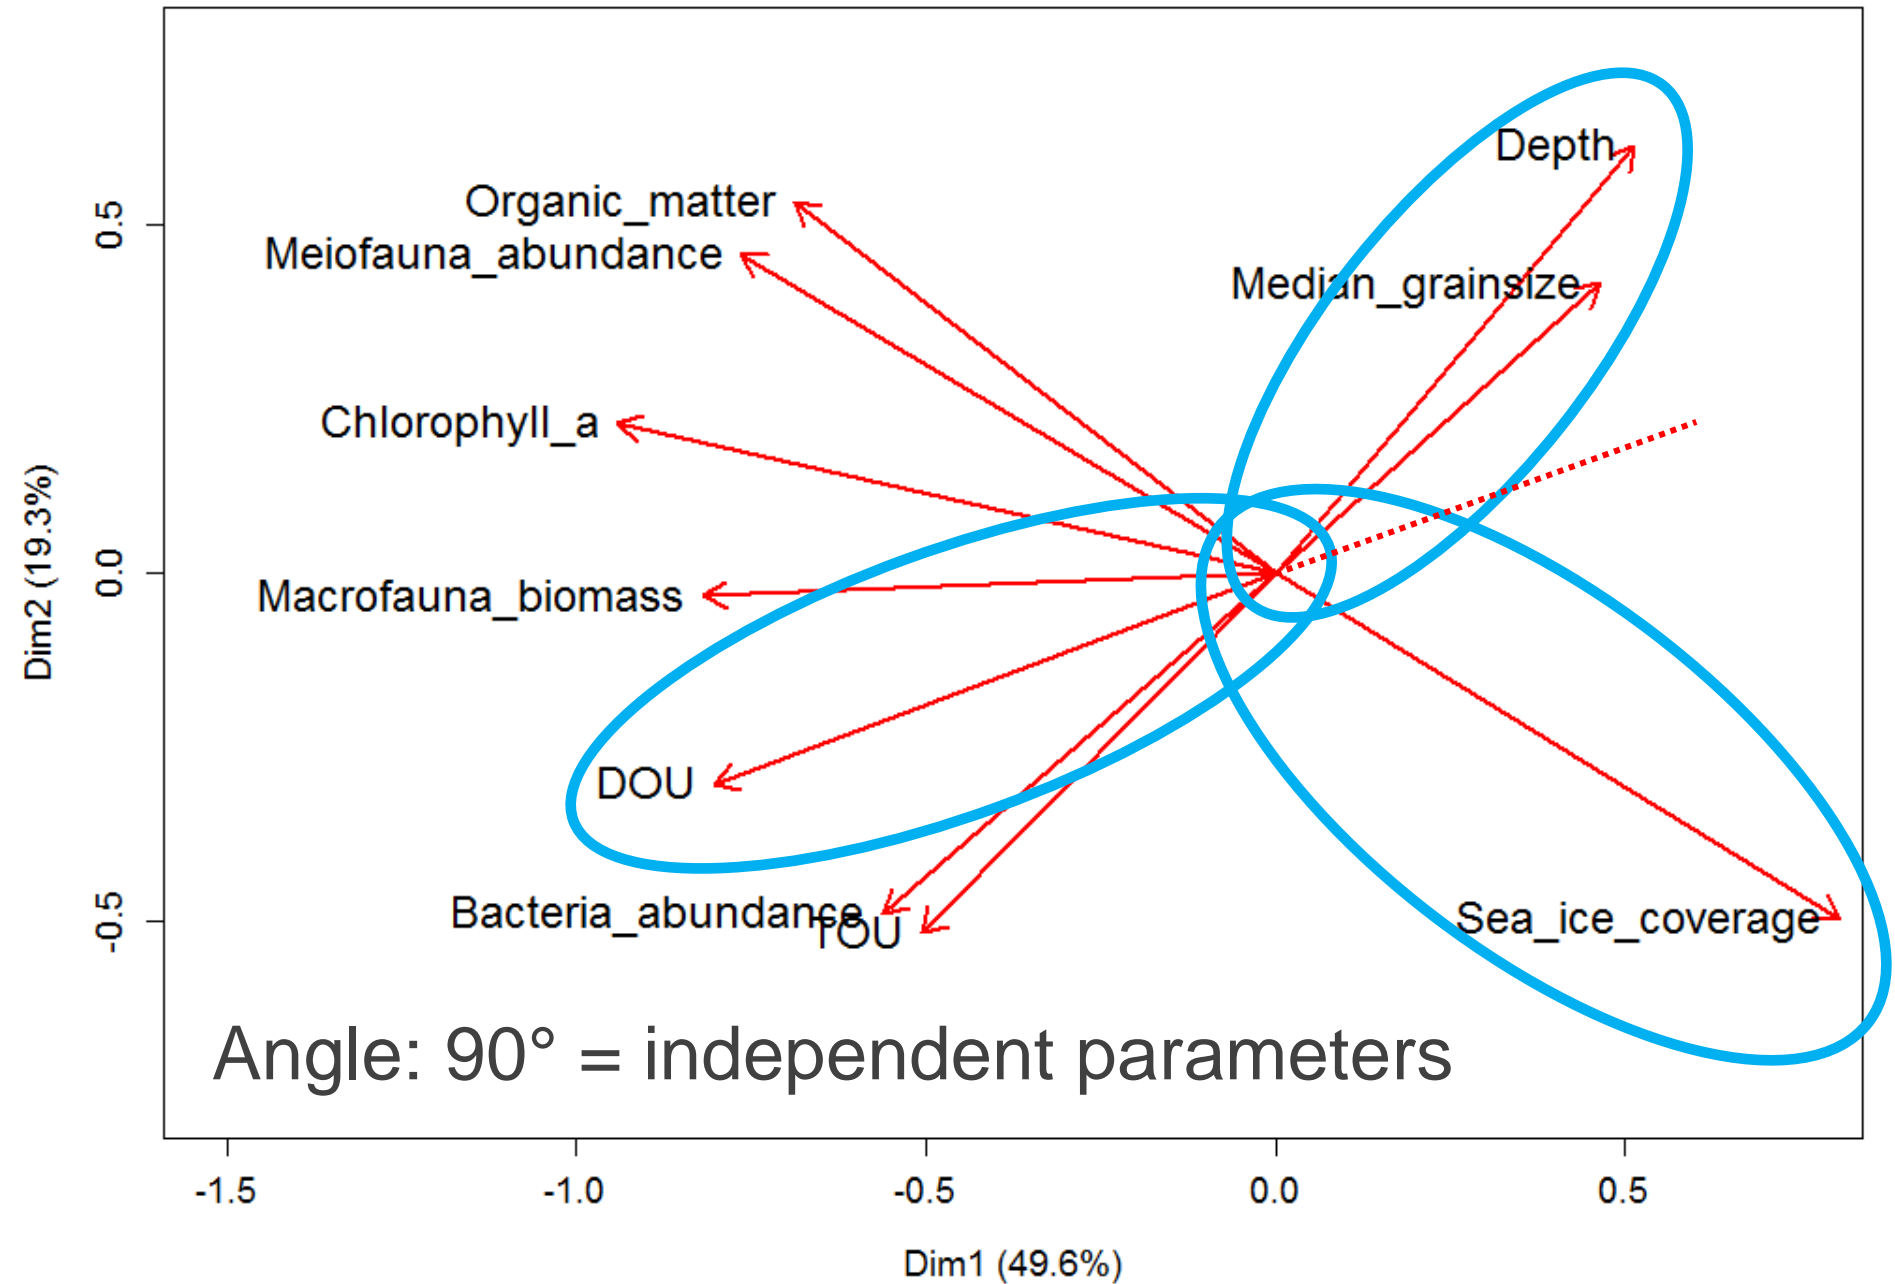

= Bacterial remineralisation

Method: Micro-profiling

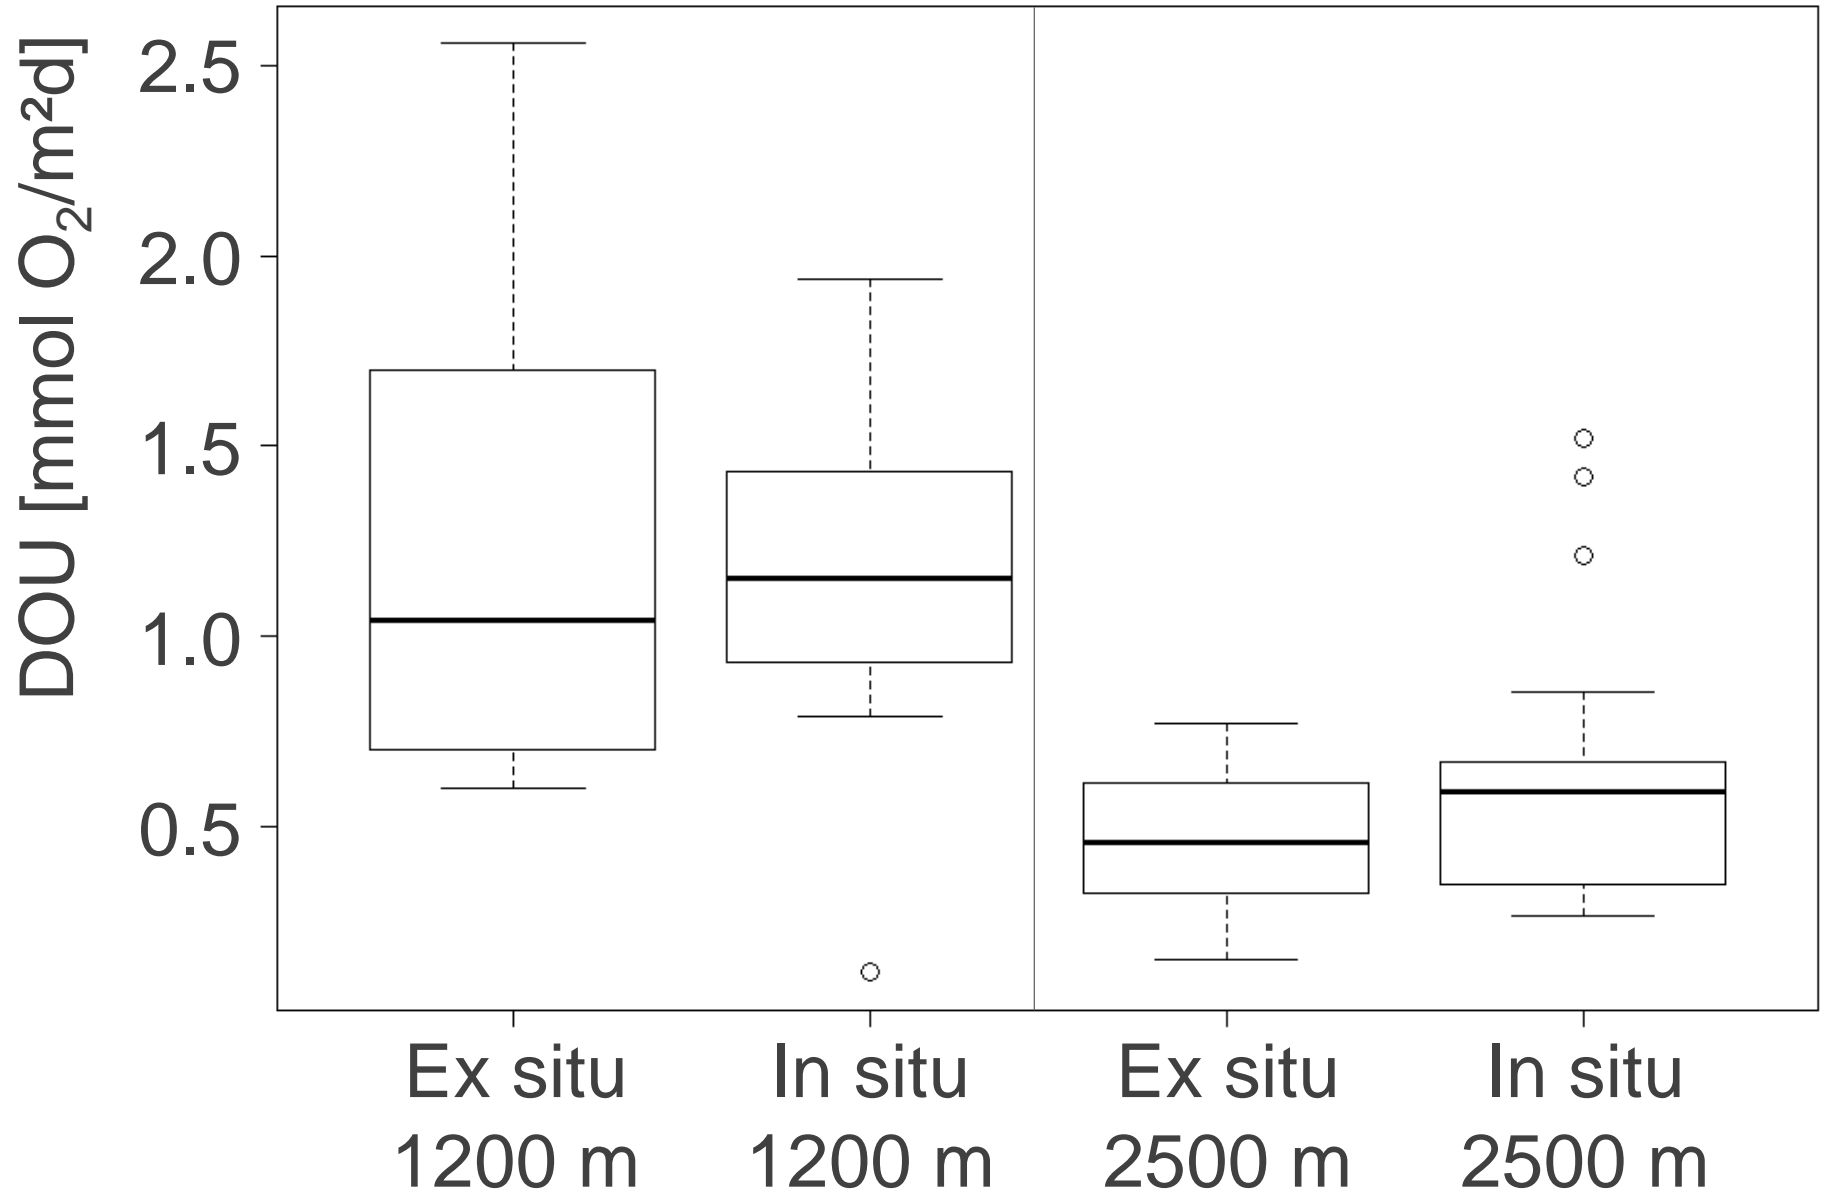

Total oxygen uptake (TOU)

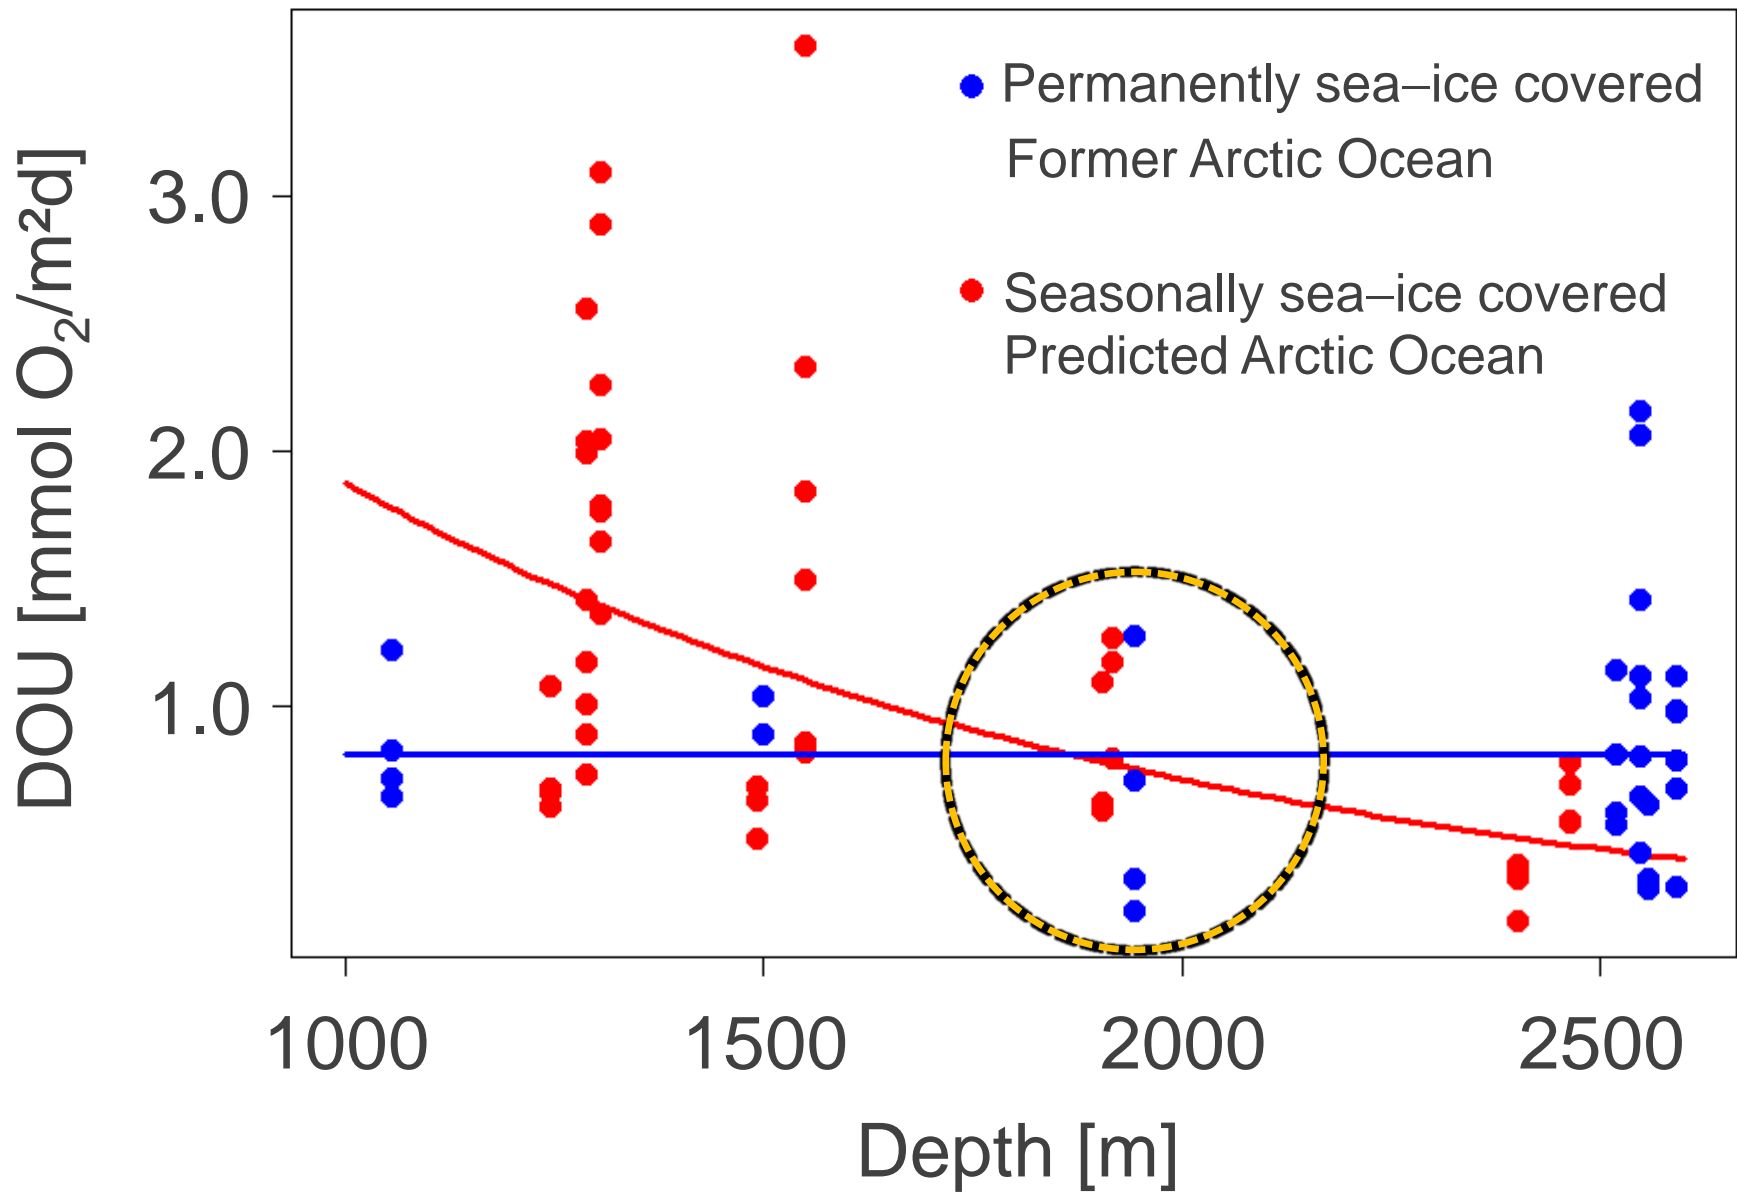

= Entire benthos remineralisation

Method: Incubation

Stations from seasonally sea-ice covered area

Are benthic
remineralsation rates
in the **Arctic deep sea** influenced by
decreasing sea-ice coverage and
increasing primary production?

How?

Answer:

**Remineralisation rates will shift
towards depth dependency**

**Increasing rates are expectable for
depth < 2000 m**

Sampling

2014: 8 MUC + 2 Lander stations

Mid – End of June

Depth: 1000 – 2500m

2015: 8 MUC + 2 Lander stations

End of July – Mid of August

Depth: 275 – 2600m

Four stations in both years

Two bathymetric transects

Test of compatibility of data

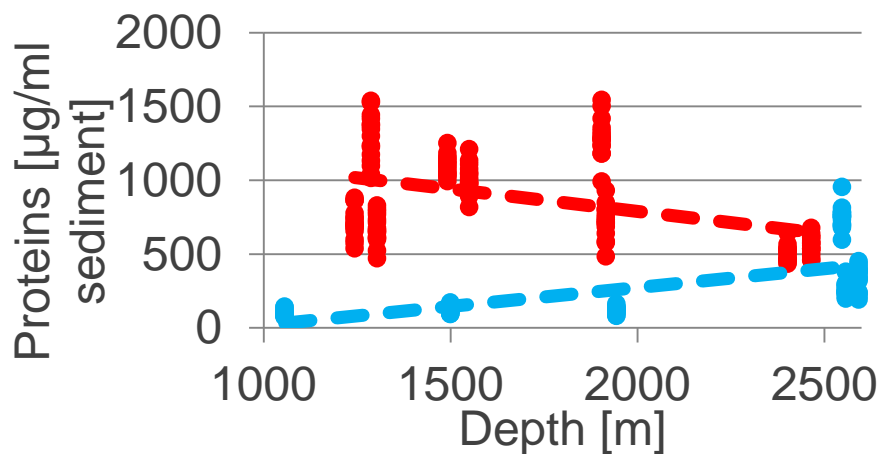

PCA on data biogenic data = not compatible

Wilcoxon: $p > 0.05$ = compatible
(Cathalot et al., Plos ONE, 2015)

Timewise differences → data over 15 years needed (Henson et al., Global Change Biology, 2016)

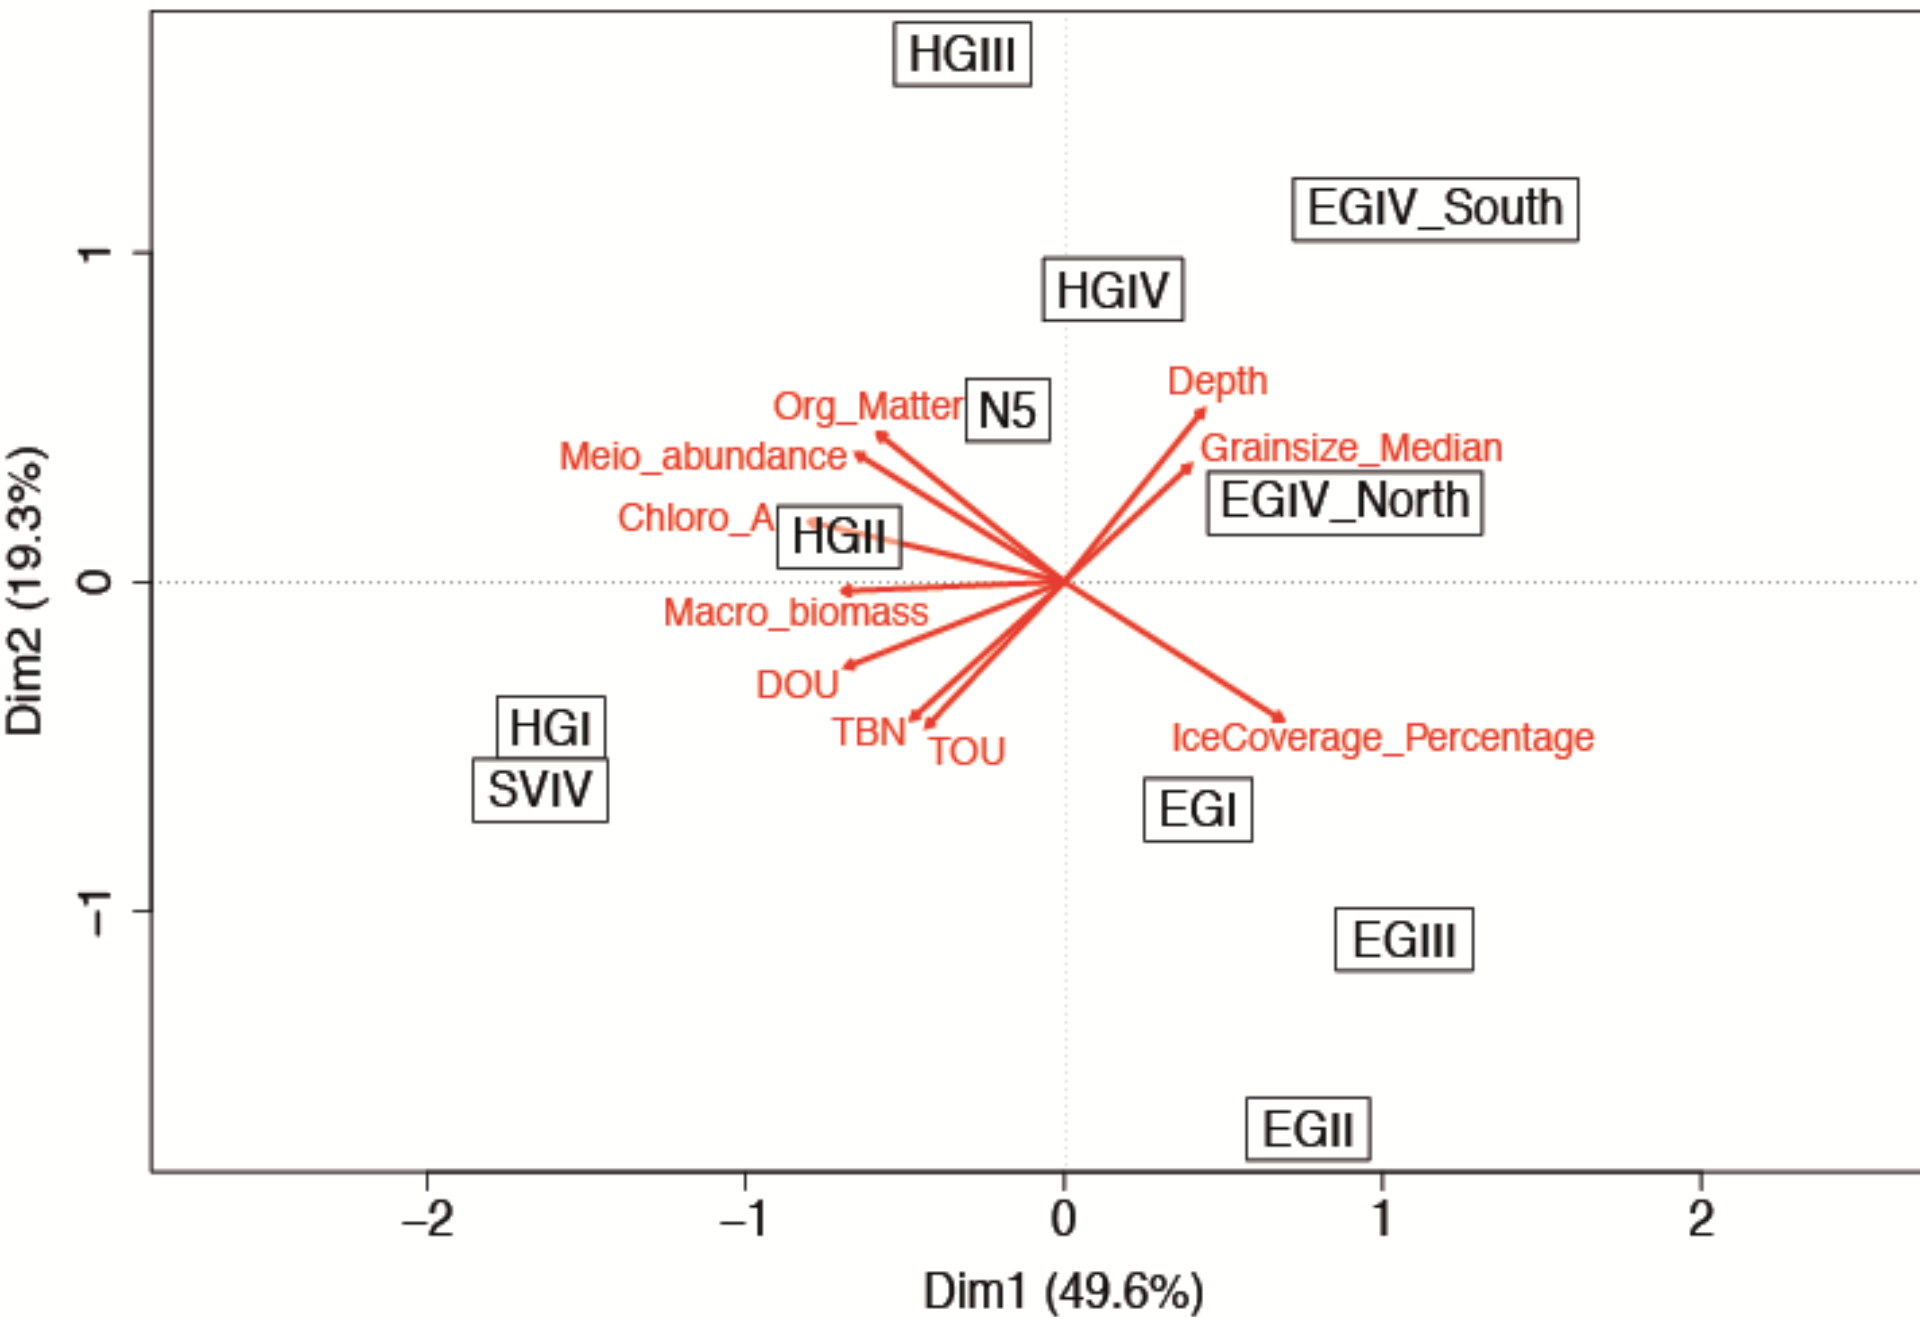

Sea-ice coverage

- High sea-ice cover
- Low sea-ice cover
- Low sea-ice cover, in situ

TOU

● High sea-ice cover

● Low sea-ice cover

● Low sea-ice cover, in situ
