Elsevier and PANGAEA Link Contents

PANGAEA research data now available for Elsevier articles

Amsterdam, 24th February 2010 — Elsevier announces that the data library PANGAEA - Publishing Network for Geoscientific & Environmental Data (<http://www.pangaea.de>) and Elsevier have implemented reciprocal linking between their respective content in earth system research. Research data sets deposited at PANGAEA are automatically linked to the corresponding articles in Elsevier journals - and vice versa.

Dr. Hannes Grobe, data librarian of PANGAEA at AWI remarks:

Through this fruitfull cooperation science is better supported and the flow of data into trusted archives is promoted. The combination of a publisher with an Open Access data respository is the ideal combination to serve the requirements of modern research by diminishing the loss of research data. It also enables the reader of a publication to verify the scientific findings and to use the data in his own work. The Elsevier-PANGAEA cooperation consequently follows the most recent recommendations of funders and international organizations about access to research data from public funding. a.o. of the

Data Description

Citation: Hesse, R et al. (1971): Holocene sedimentation in the Strait of Otranto, Mediterranean Sea. doi:10.1594/PANGAEA.707386,

Supplement to: Hesse, R; von Rad, U; Ulrich, F H (1971): Holocene Sedimentation in the Strait of Otranto between the Adriatic and Ionian Seas (Mediterranean). *Marine Geology*, 10(5), 293-355, doi:10.1016/0025-3227(71)90058-2

Abstract: An extensive radiograph study of 24 undisturbed, up to 206-cm long box and gravity cores from the western part of the Strait of Otranto revealed a great variety of primary and secondary sedimentary structures.

The regional distribution of the sediments according to their structural, textural, and compositional properties reflects the major morphologic subdivisions of the strait in shelf, slope, and trough bottom (e.g., the bottom of the northern end of the Corfu-Kephallinia Trough, which extends from the northeastern Ionian Sea into the Strait of Otranto).

(1) The Apulian shelf (0 to -170 m) is only partly covered by very poorly sorted, muddy sands without layering. These relict(?) sands are rich in organic carbonate debris and contain glauconite and reworked (?Pleistocene) ooids.

(2) The slope sediments (-170 to -1,000 m) are poorly sorted, sandy muds with a high degree of burrowing. One core (OT 5) is laminated and shows slump structures. The origin of these slumped sediment masses from older deposits higher on the slope was inferred from their abnormal compaction, color, texture, organic content, and mineral composition.

(3) Cores from the northern end of the Corfu-Kephallinia Trough (-980 to -1,060 m) display a few graded sand layers, 2–5 cm (maximum 30 cm) thick with parallel and cross-laminations, deposited by oceanic bottom or small-scale turbidity currents. They are intercalated with homogeneous lutite.

(4) Hemipelagic sediments prevail in the more southerly part of the Corfu-Kephallinia Trough and on the "Apulian-Ionian Ridge", the southern submarine extension of the Apulian Peninsula. Below a core depth of 160 cm, these cores have a laminated ("varved") zone, representing an Early Holocene (Boreal-Atlanticum) "stagnation layer" (14C age approximately 9,000 years).

The terrigenous components of the surface sediments as well as those of the deeper sand layers can be derived from the Apulian shelf and the Italian mainland (Cretaceous Apulian Plateau and Gargano Mountains, southern Apennines, volcanic province of the Monte Vulture). Indicated by the heavy mineral glaucophane, a minor proportion of sedimentary material is probably of Alpine origin. If this portion is considered to be first-cycle clastic material it reaches the Strait of Otranto after a longitudinal transport via the Adriatic Sea. The lack of phyllosilicates in the coarse- to medium-grained shelf samples might be explained by the activity of the "Apulian Current" (surface velocity 4 knots) which in the past possibly has affected the bottom almost down to depths of the shelf edge.

The percentage of planktonic organisms, and also the plankton: benthos ratio in the sediments is a useful indicator for bathymetry (depth zonation).

Community cleverness required

Researchers need to adapt their institutions and practices in response to torrents of new data — and need to complement smart science with smart searching.

Empty archives

Most researchers agree that open access to data is the scientific ideal, so what is stopping it happening? **Bryn Nelson** investigates why many researchers choose not to share.

In 2003, the University of Rochester in New York launched a digital archive designed to preserve and share dissertations, preprints, working papers, photographs, music scores — just about any kind of digital data the university's investigators could produce. Six months of research and marketing had convinced the university that a publicly accessible online archive would be well received. At the time of the launch, the university librarians were worried that a flood of uploaded data might swamp the available storage space.

Six years later, the US\$200,000 repository lies mostly empty.

or didn't understand how to use the archive, or lamented that they just didn't have any more hours left in the day to spend on this business.

As Gibbons and anthropologist Nancy Fried Foster observed in their 2005 postmortem¹, "The phrase 'if you build it, they will come' does not yet apply to IRs [institutional repositories]."

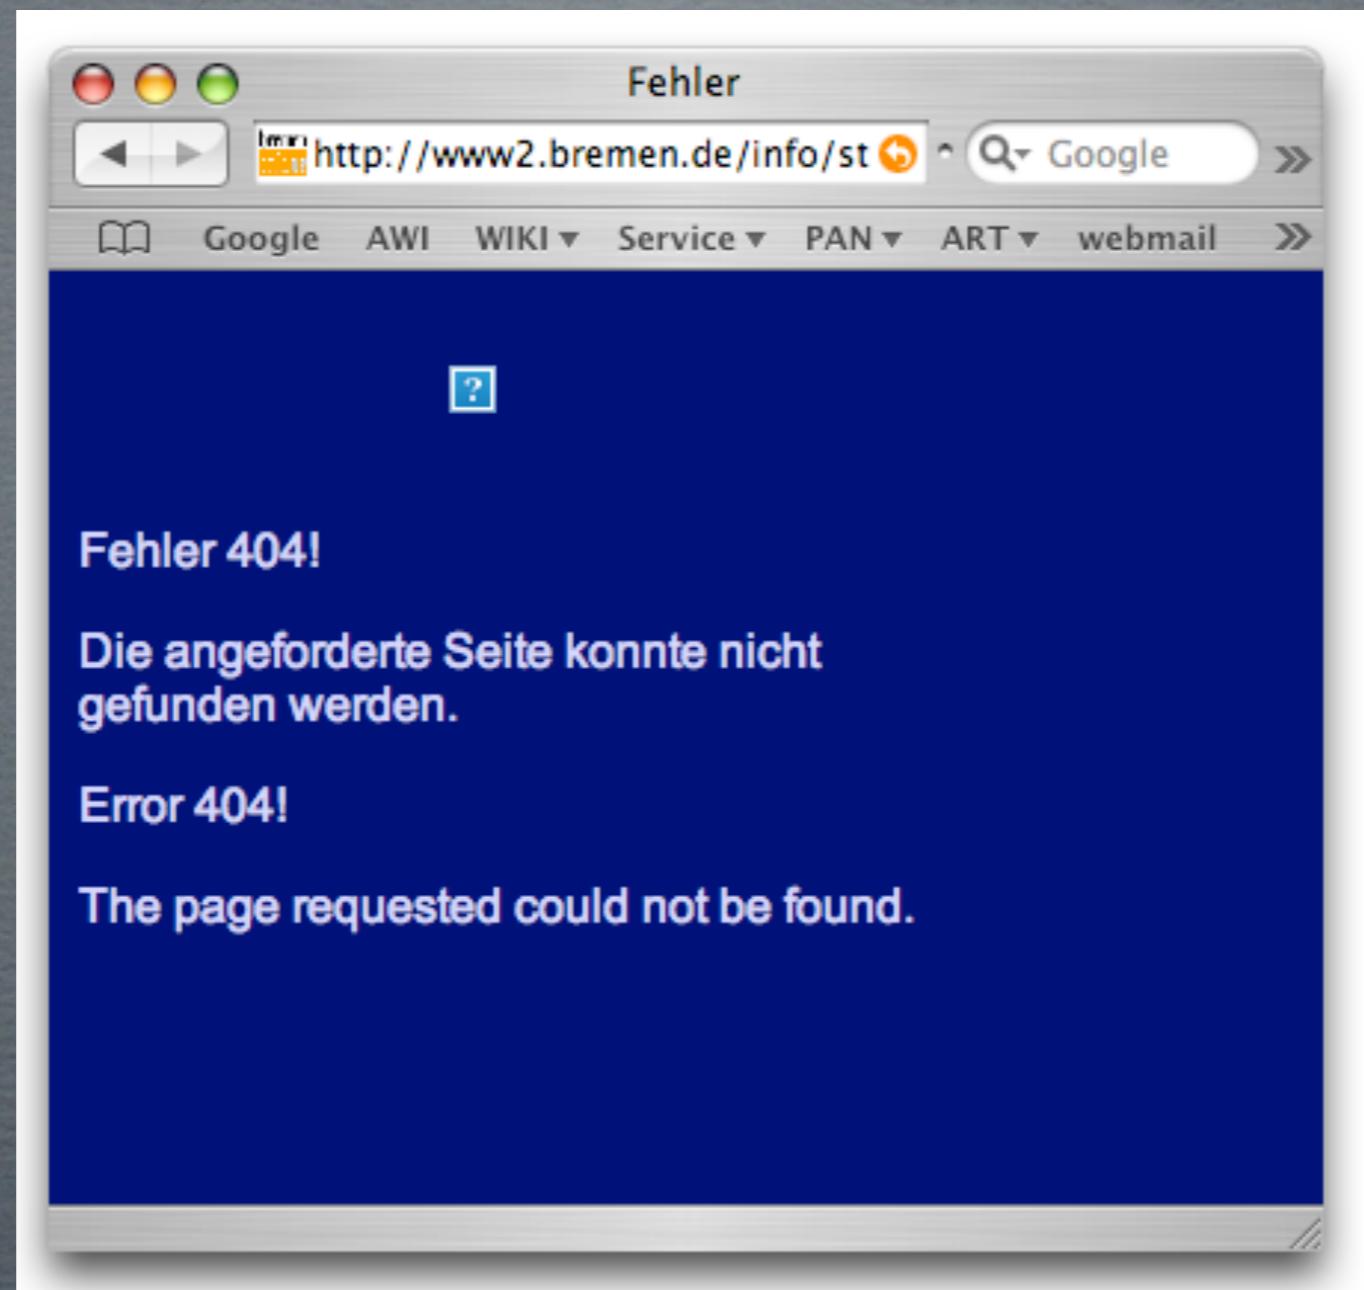

A similar reality check has greeted other data-sharing efforts. Most researchers happily embrace the idea of sharing. It opens up observations to independent scrutiny, fosters

data. Physicists, mathematicians and computer scientists use arXiv.org, operated by Cornell University in Ithaca, New York; the International Council for Science's World Data System holds data for fields such as geophysics and biodiversity; and molecular biologists use the Protein Data Bank, GenBank and dozens of other sites. The astronomy community has the International Virtual Observatory Alliance, geo-

scientists and environmental researchers have Germany's Publishing Network for Geosciences²; Environmental Data (PANGAEA),

"We got the software up and running and said 'Give us your stuff'. That's

Titel: Geological map of KVITEBOTNEN, Heimefrontfjella, Antarctica (Scale 1:25,000)

Autor(en): Jacobs, Joachim; Weber, Klaus; Zarske, G; Kreutzer, S; Spaeth, G

Erschienen in: 2004;

Verlag: PANGAEA - Publishing Network for Geoscientific & Environmental Data (Bremen/Bremerhaven)

Dokumenttyp: Forschungsdaten

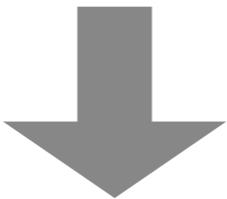

Sprache: Englisch

DOI: 10.1594/PANGAEA.138783

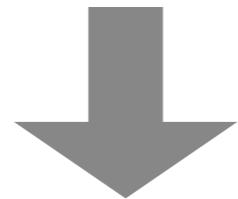

Abstract

Topographic data of this geological map were obtained through stereoscopic aerial photo interpretation. The photogrammetric photo flights were undertaken in 1986 by the Institut für Angewandte Geodäsie, Frankfurt. Horizontal ground control points required for aerial photo interpretation were determined by means of Doppler satellite observation during the 2nd German Neuschwabenland Expedition 1985/86. Vertical ground control points were taken from unpublished map drafts at 1:100 000 scale by Norsk Polarinstitutt, Oslo. The elevation above mean sea level was transferred to Heimefrontfjella barometrically. For this reason assertions concerning the absolute elevation (referred to sea level) are uncertain. Contours and spot heights presented on the map were obtained from the photogrammetric evaluation of the photography taken in 1986; relative elevation data (height differences) are accurate to approximately ±10 m.

Bremerhaven, Germany

Abstract. On 22 May 1985 the first balloon-borne ozonesonde was successfully launched by the staff of Georg-Forster-Station (70°46' S, 11°41' E). The following weekly ozone soundings mark the beginning of the continuous investigation of Germany to study the vertical ozone distribution in the southern hemisphere.
