1. Introduction

During the spring of 1983 a multidisciplinary oceanographic experiment was carried out in the Norwegian Trench between the Skagerak and Latitude 60°N. The major aim of this investigation was to map the coastal current system which comprises the main outflow of water masses from the North Sea. Special emphasis was put on the observation of the spatial structure and temporal variability of this part of the large scale circulation which is strongly influenced by topographic effects and the forcing by the atmosphere. Secondary objectives were to study mesoscale features associated with this current system and the spring development of the plankton bloom.

The experiment was carried out jointly by the Institut für Meereskunde (University of Hamburg), the Geophysical Institute (University of Bergen) and the Institute of Marine Research (Bergen). It included the deployment of 14 current meter moorings, covering the Norwegian Trench off Utsira and Egeroy, and hydrographic and biological surveys by RV VALDIVIA and RV HAKON MOSBY, occupying more than 300 stations.

This report describes the hydrographic data collected during RV VALDIVIA's cruise 10 between 23 March and 17 April 1983. The current meter and biological data from RV VALDIVIA and the hydrographic data from RV HAKON MOSBY will be published in subsequent reports.

The sampling schemes of the hydrographic parameters were designed to fit the different scales associated with the processes to be investigated. On the large scale six sections perpendicular to the coast were occupied between 7°30'E and 59°50'N, sampling at nominal intervals of 5 nautical miles (L1-6. in Fig. 1). Section L3 off Egeroy was sampled a total of 14 times during the experiment to map the temporal variability of the large scale flow field.

Two areas were chosen for detailed high resolution mesoscale studies (Figs. 1 and 2). One off the Boknafjord between sections L4 and L5 and one off Egeroy in the vicinity of section L3. The latter area was densely sampled two times to obtain an almost synoptic view of the hydrographic field at the location of the small scale mooring array.

The data are displayed in several section plots and maps, showing the

spatial distribution and the variability in time of the hydrographic parameters. Given in the appendix are listings of these parameters at standard depth levels for each station, including pressure, depth, temperature, salinity, potential temperature, potential density, dynamic height anomaly and Brunt- Väisälä frequency.

2. Data collection and processing

Altogether 290 vertical profiles of temperature and salinity were taken, employing a ME-Multisonde CTD supplemented by a 6 bottle rosette sampler. The CTD provided data with a resolution of 1.5 m deg, 0.2 dbar and 0.002 mS/cm at a rate of 0.5 Hz which were recorded on a Kontron Psi 80 computer and stored on digital floppy disks. Only data from the lowering profiles, run at a speed of 0.7 m/s, were processed. On recovery the instrument was stopped at several depth levels to operate the rosette sampler, thereby providing calibration data for salinity. Due to electronical and mechanical problems with the sampler only about 40 water samples were taken. In addition surface data of temperature and salinity were obtained from bucket samples. Salinities of the samples were analysed on board by use of a Beckmann salinometer.

The few in-situ calibration data confirmed the calibration of the CTD carried out before the cruise in the laboratory. The data can therefore be regarded as being accurate to within $\delta T = \pm 0.02^\circ\text{C}$ for temperature, $\delta S = \pm 0.01 \text{ ‰}$ for salinity and $\delta p = \pm 3 \text{ dbar}$ for pressure.

After editing obviously erroneous data through linear interpolation between neighbouring values the vertical profiles were averaged within intervals of 5 dbar, centered at 0, 5, 10, 15 dbar etc. These data served as a basis for the plots and the hydrographic listings given in the appendix.

3. Some remarks on the observations

Large scale hydrographic structure

The vertical distributions of temperature, salinity and density along the large scale sections L1 to L6 (Fig. 1) which were occupied between 27 March

and 2 April 1983 are shown in Figs 3 to 8.

The general pattern of watermass distribution resembles the well known structure of the current system of the Norwegian trench during early spring. The coastal current, characterized through low temperatures and salinities, alignes along the coast with isolines sloping downward towards the coast. On the western slope of the trench the core of high salinity water documents the inflow of water from the Atlantic. Both, temperatures and salinities, decrease southward from section L6 to L1 in the two flow regimes presumably due to lateral mixing of the two watermasses.

Temporal variability

Section L3 off Egeroy was occupied 14 times between 23 March and 18 April. Rather than showing the individual section plots as above we have plotted the distribution of the parameters at the surface and at 30m and 100 m depth in a time-space diagram (Figs. 9-11).

At the surface salinities across the front of the coastal current range from a low of 28‰ near the coast to more than 35‰ over the North Sea shelf. The front shows some meandering with time scales between 3 and 15 days, presumably due to the passage of mesoscale eddies. The sharp front running perpendicular to the coast at the beginning of the measurement period around 25 March is probably due to the passage of an internal Kelvin wave associated with an outbreak of low salinity water from the Skagerak. The mesoscale variability is also reflected in the surface temperature pattern which in addition shows the effects of the spring warming by more than 1°C over the four weeks measurement period.

At 30m and 100m depth the position of the front is closer to the coast compared to the surface layer. Also the mesoscale features are much less pronounced, indicating that they are mostly contained in the first baroclinic mode.

Mesoscale surveys

- a) southern area 2. - 3. April 1983

The distribution of hydrographic parameters at the surface, at 30 m and

100 m depth (Figs. 12-14) shows strong meandering of the front between the coastal current and the Atlantic inflow. The spatial scales of these meanders, which are most pronounced at the surface, range between 20 and 40 km making vertical shear instability the most likely process for their generation.

b) northern area 6. - 8. April 1983

In the northern mesoscale survey area around 59°N the spatial scales of the front meanders (Figs 15-17) are much larger than in the southern region and range between 50 and 80 km. Here the current system follows the topographic bump as indicated in the 200 m contour in Fig. 1. The pronounced anticyclonic eddy found on section L5 about 10 days earlier was not present any more during this survey and had apparently drifted northward.

c) southern area 8. - 10. April 1983

As during the first mesoscale survey the spatial scales of the frontal patterns range around 30 km (Figs 18-20).

Acknowledgements

We thank captain and crew of RV VALDIVIA for their support during the measurements. Peter Damm, Norbert Kersten and Klaus Schulze assisted in the data collection. Financial support by Deutsche Forschungsgemeinschaft within Sonderforschungsbereich 94 is gratefully acknowledged.
