Reducing the uncertainty in projections of future ice shelf basal melting

Ralph Timmermann, Frank Kauker, Hartmut Hellmer (AWI)  
Willem Jan van de Berg (IMAU, Utrecht University)

Introduction
Simulations of ice shelf basal melting in the future climate scenarios proposed in the IPCC’s Fourth Assessment Report (AR4) have revealed a large uncertainty and the potential of a rapidly increasing basal mass loss particularly for the large cold-water ice shelves in the Ross and Weddell Seas. The large spread in model results was traced back to uncertainties in the freshwater budget on the continental shelf, which is governed by sea ice formation. Differences in sea ice formation, in turn, follow the regional differences between the atmospheric heat fluxes imprinted by the climate models. A more recent suite of model experiments was performed with output from two members of the newer generation of climate models engaged in the IPCC’s Fifth Assessment Report (AR5). Comparing simulations forced with output from the AR5/CMIP5 models HadGEM2 and MPI-ESM, we find that uncertainties arising from inter-model differences in high latitudes have reduced considerably.

Modeling strategy
• Finite Element Sea-ice Ocean Model (FESOM; Timmermann et al., 2012)
• 3-equation model of ice-ocean interaction
• global domain, resolution varying from 4° to 2.5°
• hybrid vertical coordinate: 36 z-levels, 23 of which turn into sigma-levels on the Antarctic continental slope (above 2500 m) and enter the cavities
• ice shelf and ocean bottom topography: RTopo 1 (Timmermann et al., 2010)
• forcing from ECHAM5-MPIOM and HadCM3 for AR4 scenarios E1 and A1B
• forcing from mpi-ems and HadGEM2 for AR5 scenarios RCP4.5 and RCP 8.5

FESOM domain and discretization

FESOM domain and discretization

Reducing uncertainty: AR5 scenarios
• experiments with output from AR5/CMIP5 models
• scenarios RCP 8.5 („worst case“, blue lines) and RCP 4.5 (moderate, red lines)
• difference in surface freshwater flux strongly reduced
• for the ice shelves in the Weddell Sea difference between scenarios is now bigger than between models
• for Amundsen and Bellingshausen Seas, the Hadley model still gives the larger increase (for both scenarios), but the difference between the models has reduced a lot.

Outlook
Coupling FESOM to the Regional Atmospheric Climate Model (RACMO)
• joint project with University Utrecht (W.J. van de Berg and M. van den Broek)
• 27 km resolution regional atmosphere model
• boundary conditions from
  1. ERA-interim reanalysis
  2. Climate model future scenarios
• PhD thesis Marta Anna Kasper
  (to be done, but please go see her poster)

Summary
• AR5 projections of heat fluxes / FESOM sea ice formation rates over the Southern Ocean continental shelves have converged to an ensemble with a much smaller spread than between the AR4 experiments.
• Gradual but accelerating increase of basal melt rates during the 21st century is robust for most ice shelves
• Basal melt rates for Filchner-Ronne Ice Shelf in FESOM consistently double by the end of the 21st century in the RCP85 scenario.
• For the smaller, warm-water ice shelves, inter-model differences in ice shelf basal mass loss projections are still slightly larger than differences between the scenarios.
• Compared to AR4 projections, the model-dependent spread has been strongly reduced.
