Special Issue 83: Drilling through the ice

DOI: [10.1017/aog.2020.76](https://doi.org/10.1017/aog.2020.76)

Abstract

Ever since the first deep ice cores were drilled, it has been a challenge to determine their original, in-situ orientation.

In general, the orientation of an ice core is lost as the drill is free to rotate during transport to the surface.

For shallow ice cores, it is usually possible to match the adjacent core breaks, which preserves the orientation of the ice column.

However, this method fails for deep ice cores, such as the EastGRIP ice core in Northeast Greenland.

We provide a method to reconstruct ice core orientation using visual stratigraphy and borehole geometry.

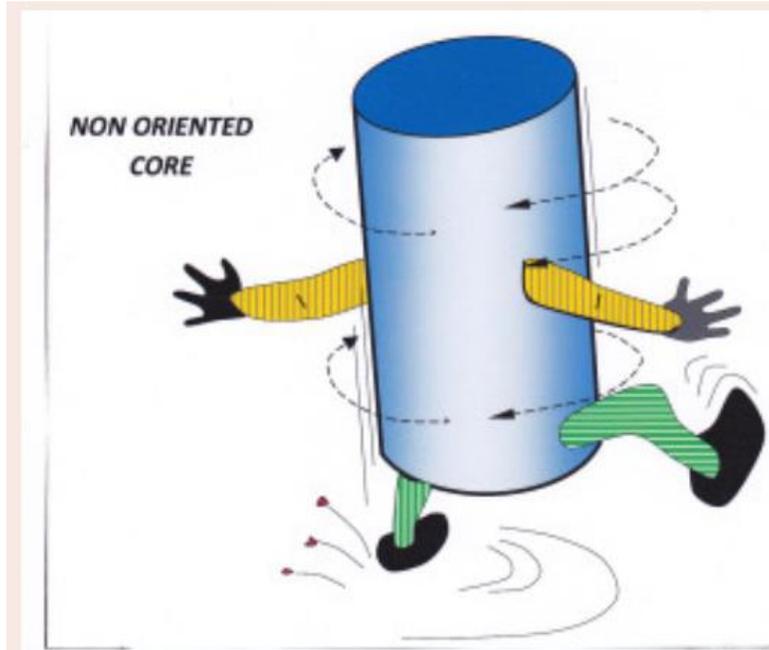

As the EastGRIP ice core is drilled through the Northeast Greenland Ice Stream, we use information about the directional structures to perform a full geographical re-orientation.

We compared the core orientation with logging data from core break matching and the pattern of the stereographic projections of the crystals' c-axis orientations.

Both comparisons agree very well with the proposed orientation method.

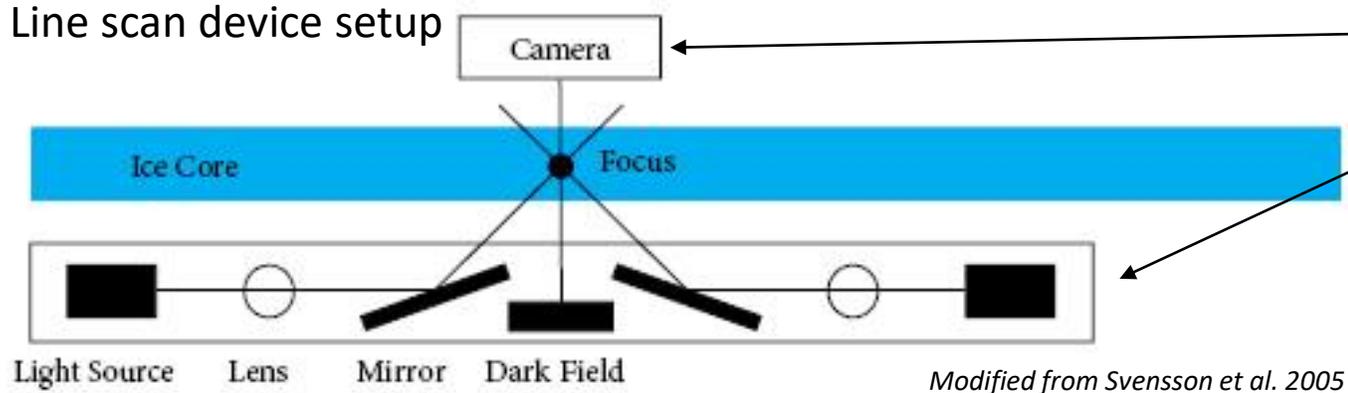

The method works well for 441 out of 451 samples from a depth of 1375–2120m in the EastGRIP ice core.

It can also be applied to other ice cores, providing a better foundation for interpreting physical properties and understanding the flow of ice.

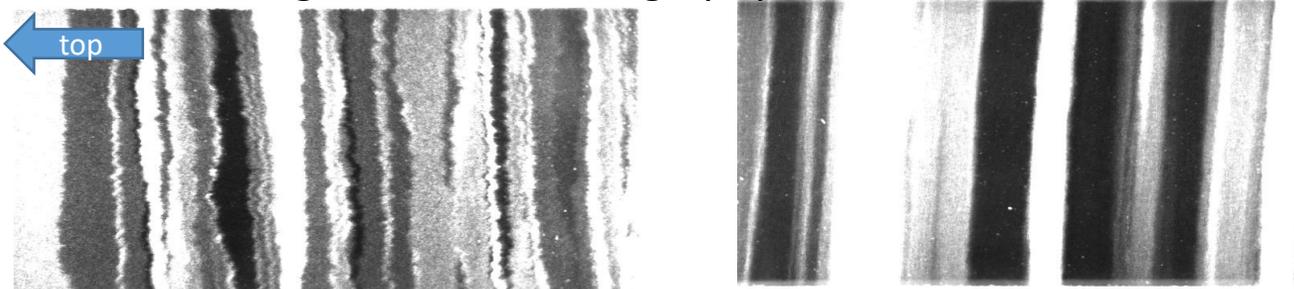

Line scan device setup

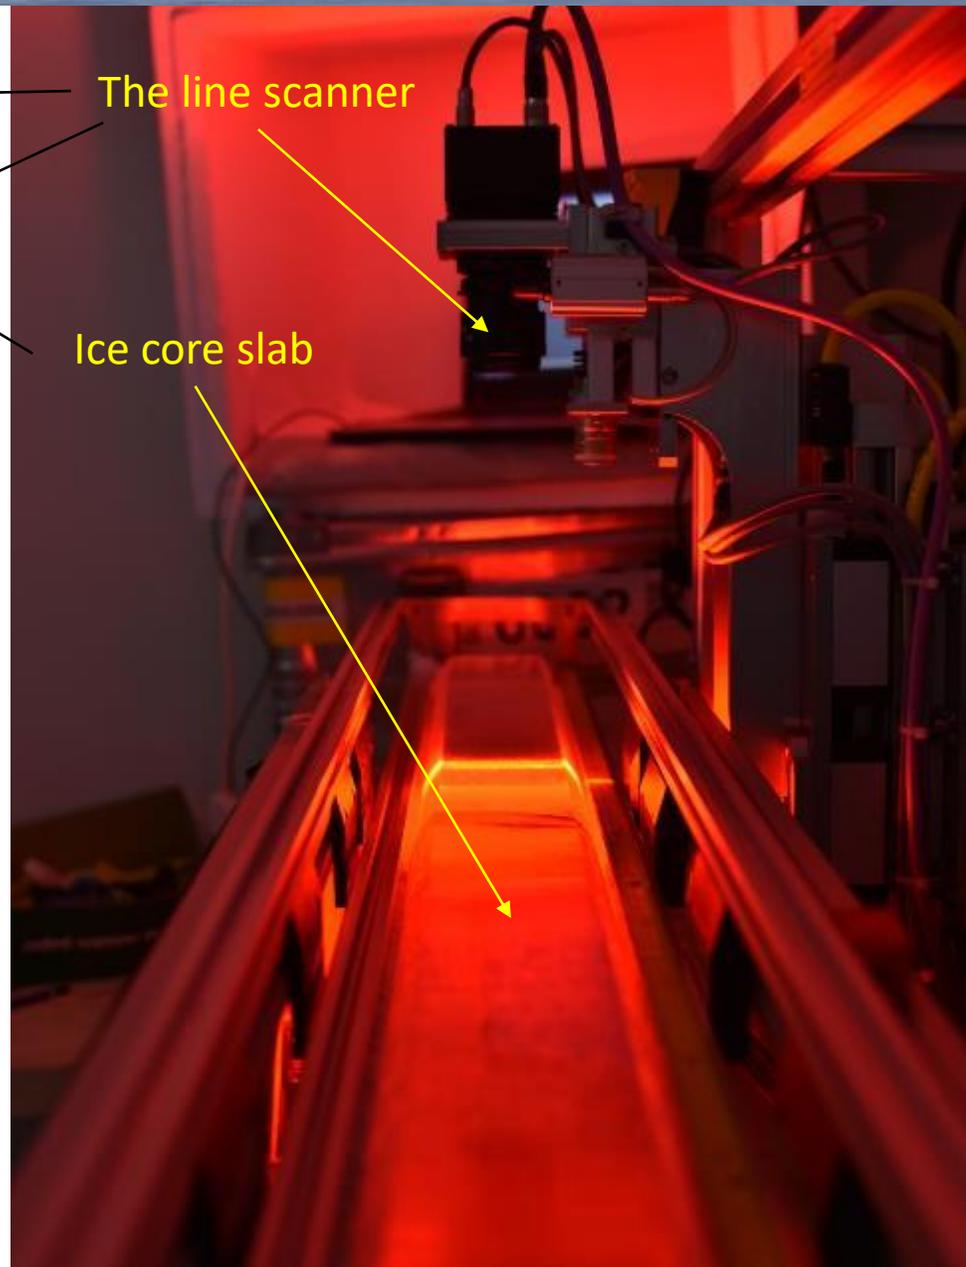

The line scanner

Ice core slab

Line scan images or visual stratigraphy

- Bright sections: reflection/scatter of light from trapped air, fractures, dust, or others
- Dark sections: no reflection/scattered due to "clean" ice

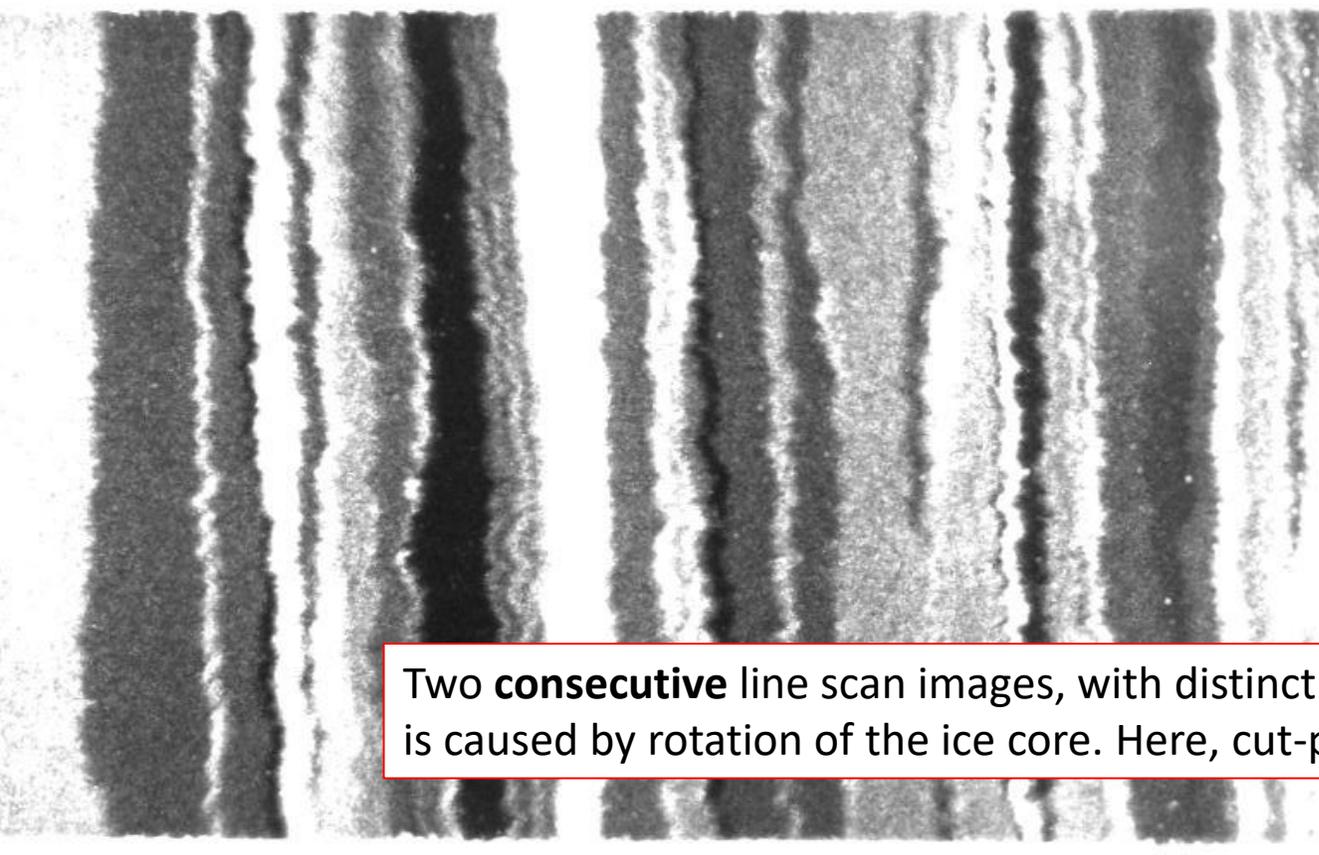

| 1633.95m

| 1634.00m

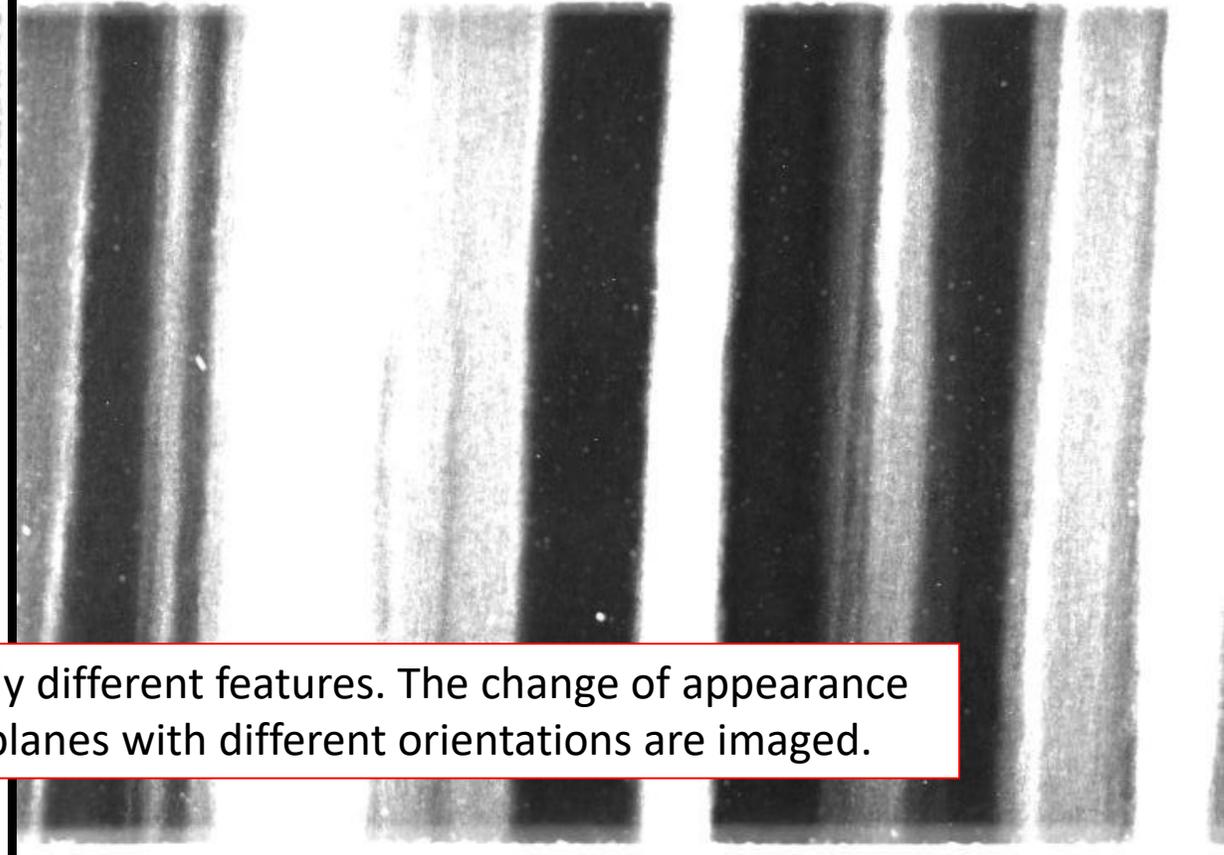

| 1634.05m

| 1634.10m

1634.15m |

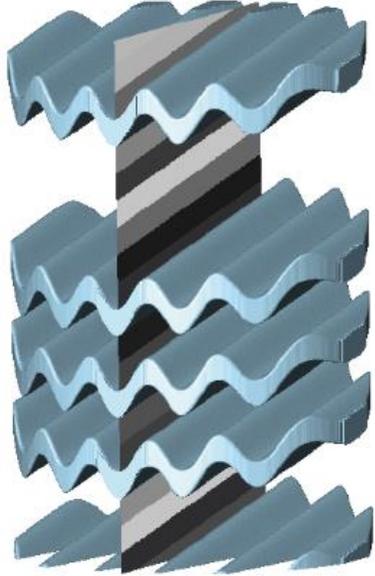

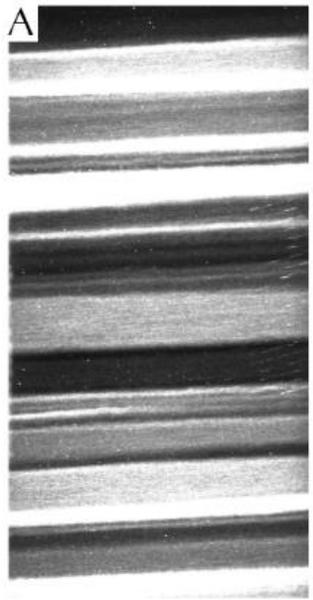

Two **consecutive** line scan images, with distinctly different features. The change of appearance is caused by rotation of the ice core. Here, cut-planes with different orientations are imaged.

Sketch of the 3D structures

Imaged plane is:
- parallel to folds,

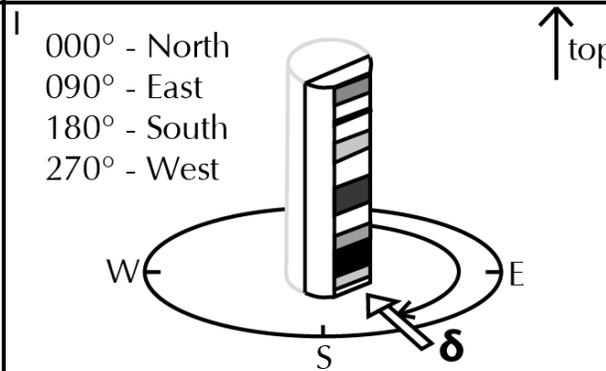

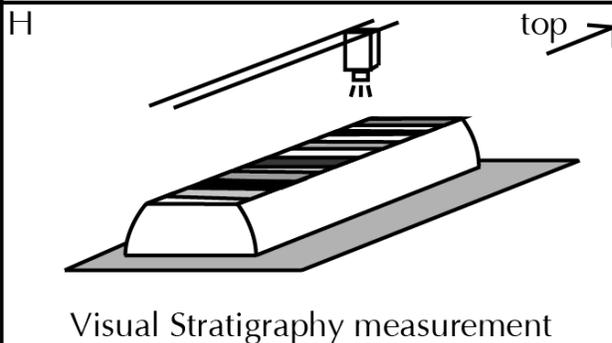

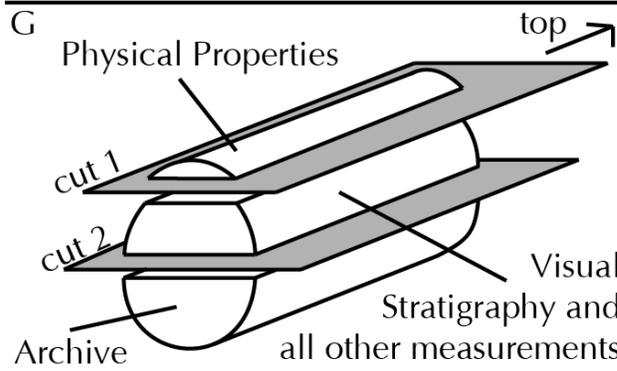

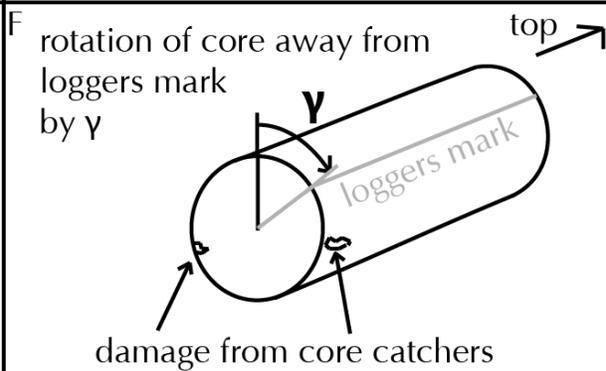

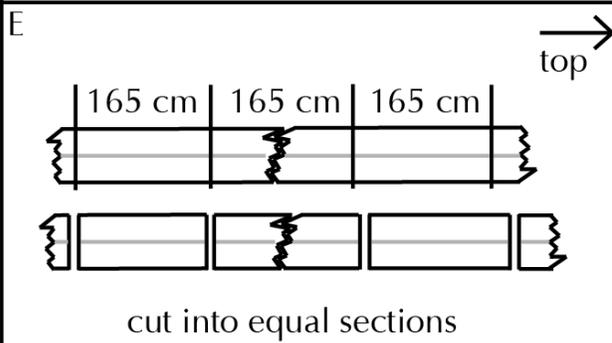

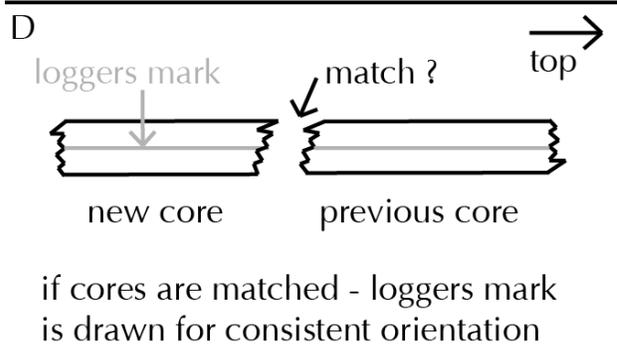

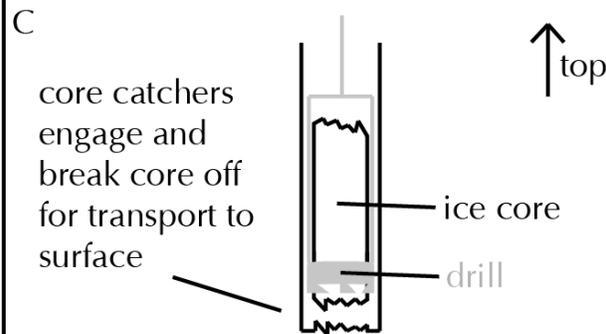

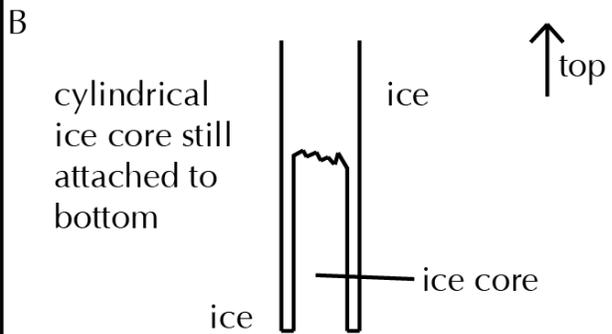

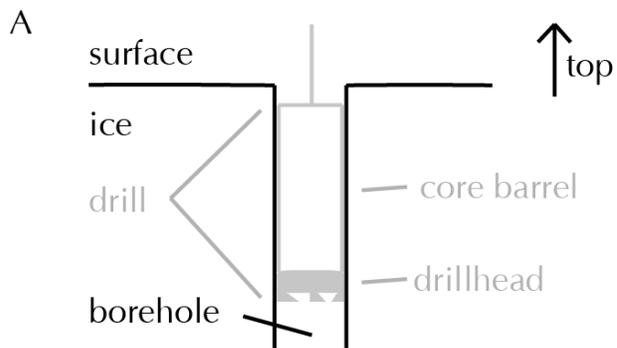

- at an angle to folds, and

- perpendicular to folds.

An Ice Core's Journey

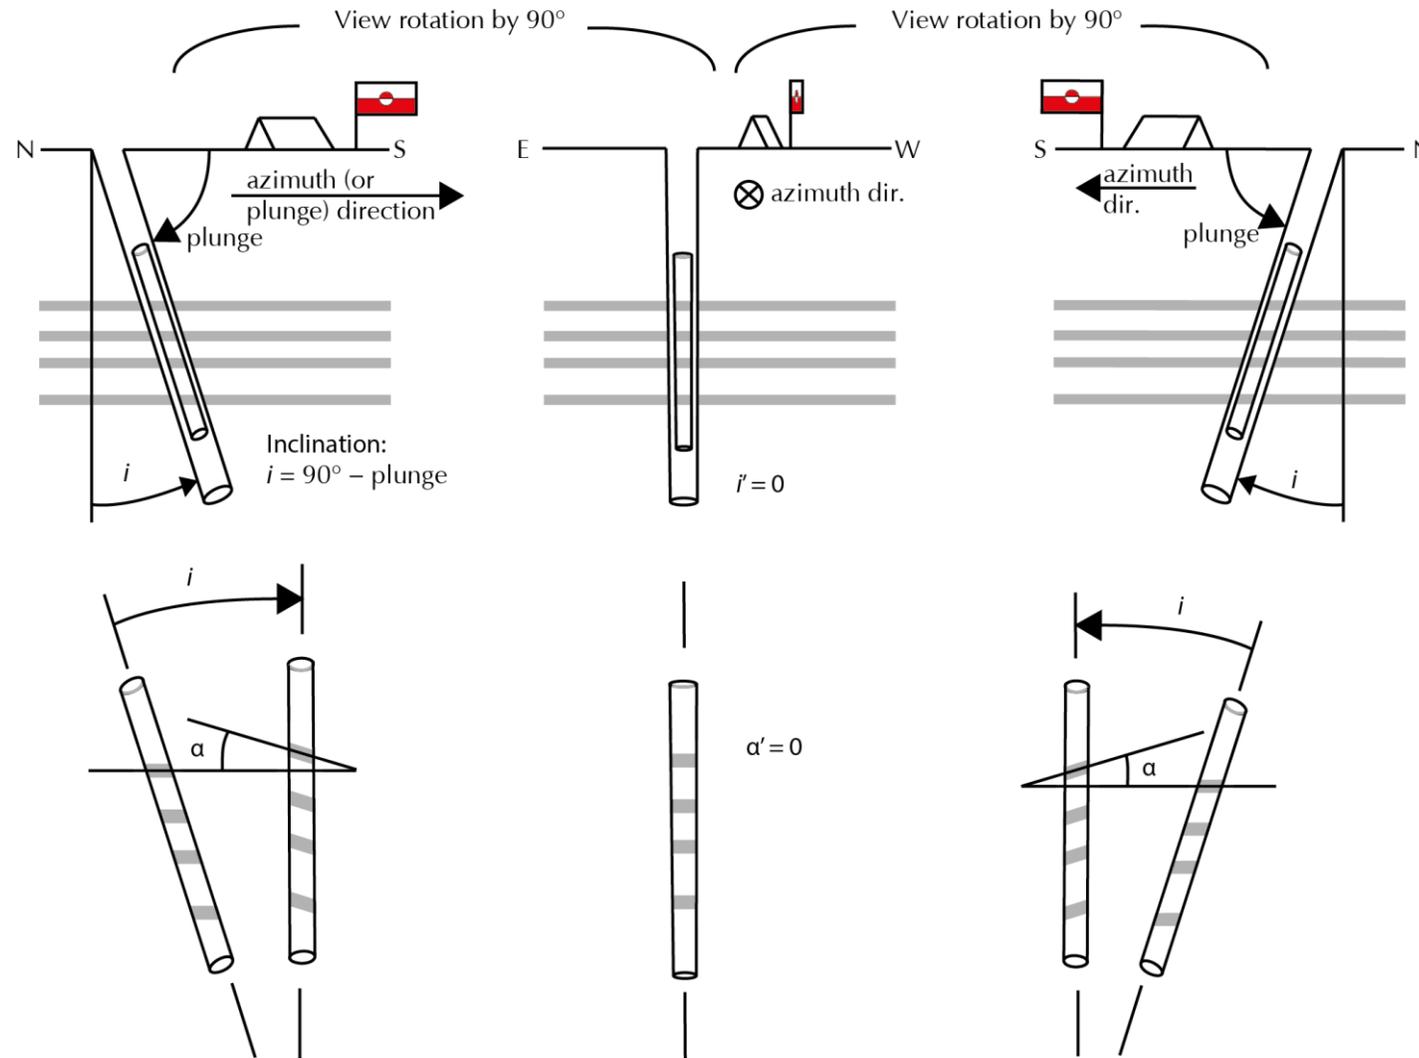

An ice core's journey – from the bottom of the ice sheet to the measurement table

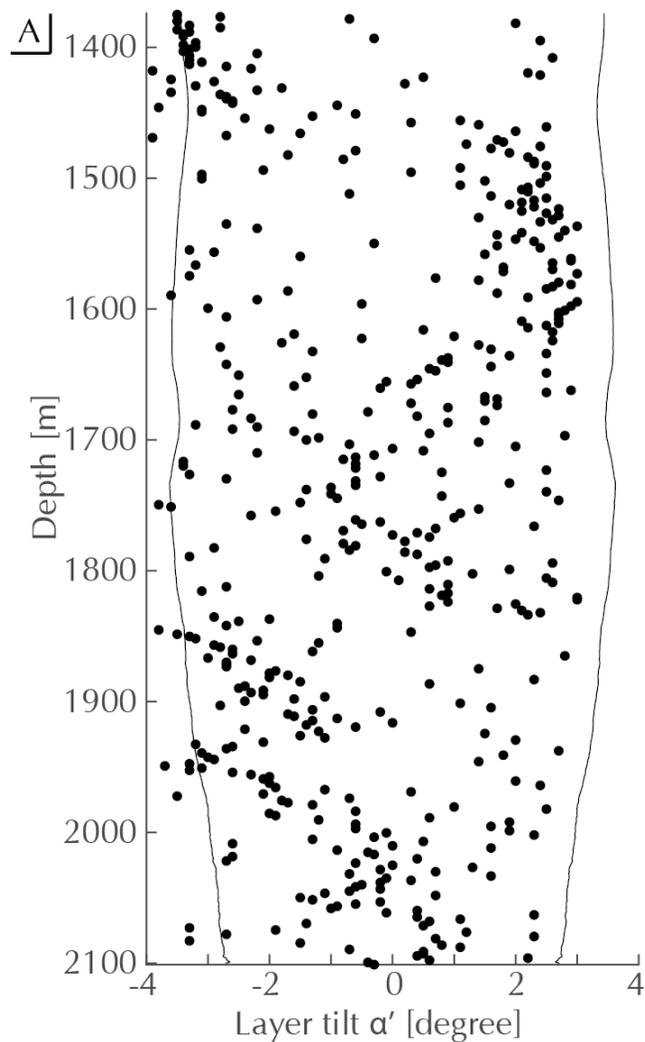

C) Orientation of ice core is lost, as drill is free to rotate during transport to the surface.

D) relative orientation is restored. (relative to previous run)

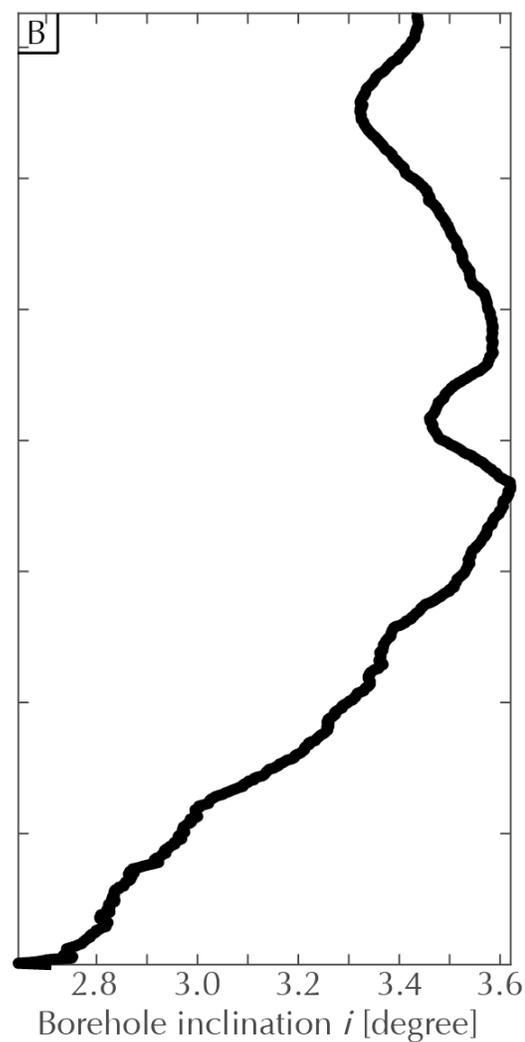

I) reconstruction of ice core orientation.

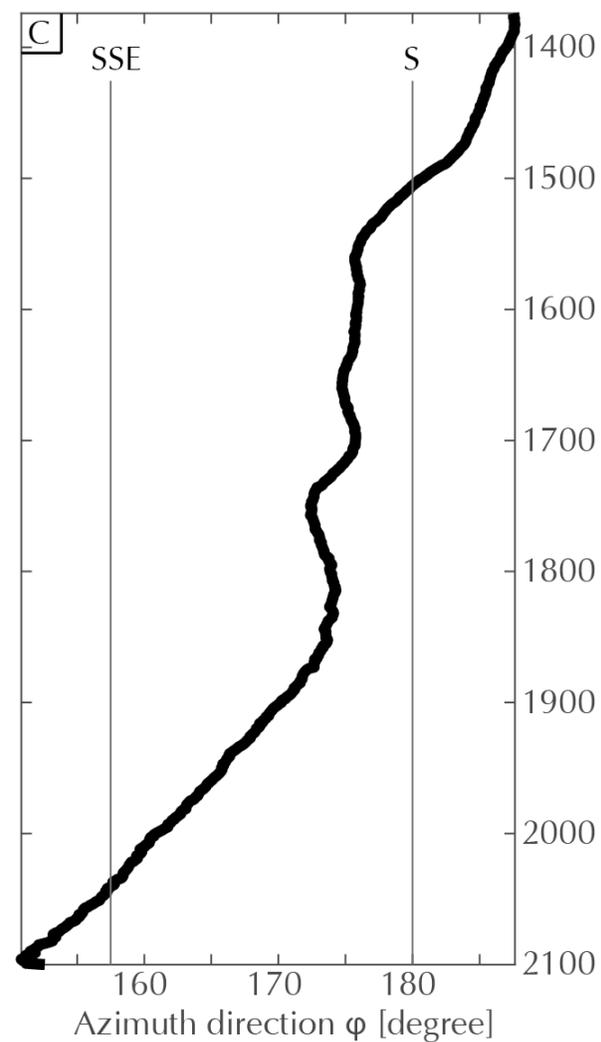

The inclination of horizontal layers changes, when the bore hole is inclined and then viewed from different angles.

A) measured tilts of layers
in the EastGRIP ice core.

B) borehole inclination

C) azimuth direction.

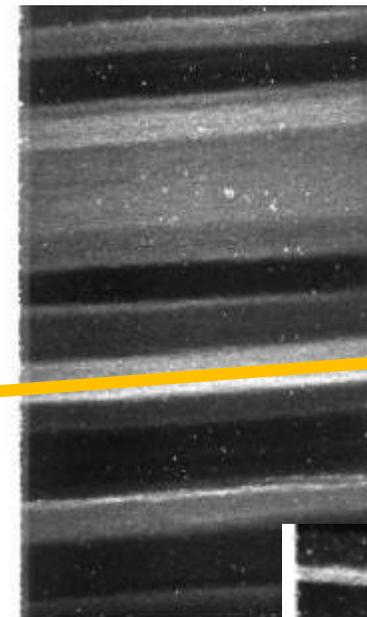

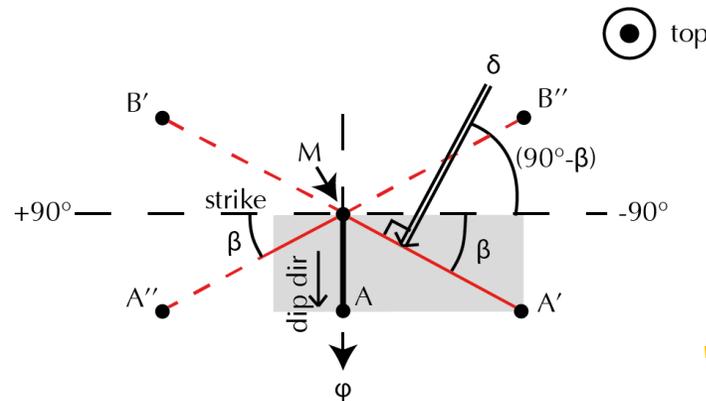

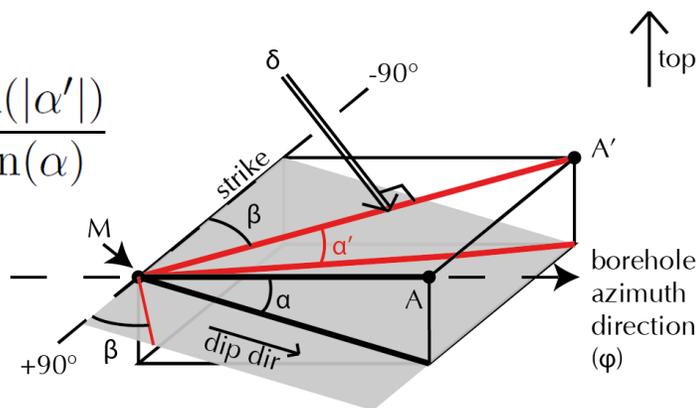

If we know the
tilt/inclination of each
layer and the borehole
geometry, then we can
reconstruct the ice core
orientation.
See next slide.

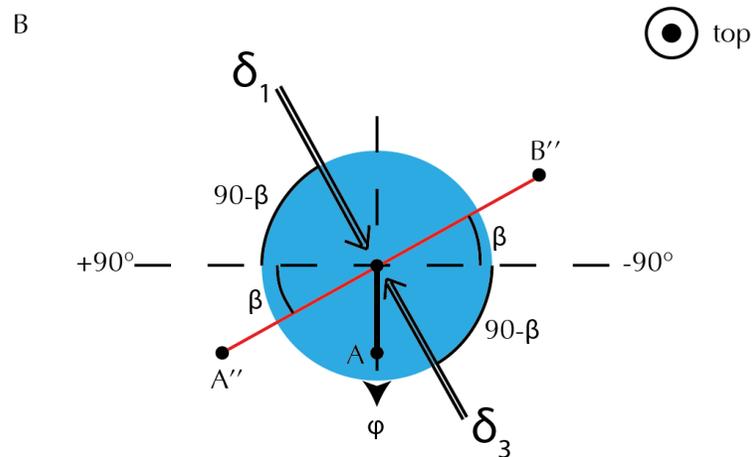

The Method

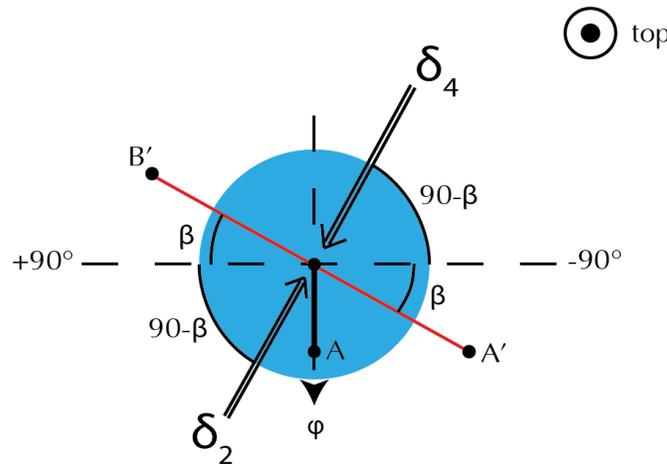

$$\sin(\beta) = \frac{\tan(|\alpha'|)}{\tan(\alpha)}$$

negative tilt
 $\delta_{(1,2)}$

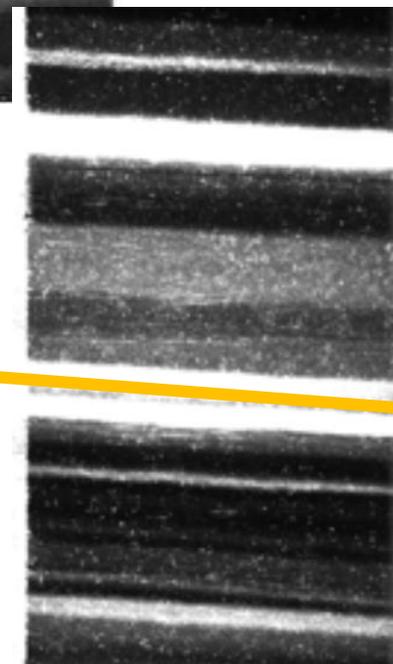

$$\delta_{(1,2)} = \varphi + 90 \pm (90 - \beta)$$

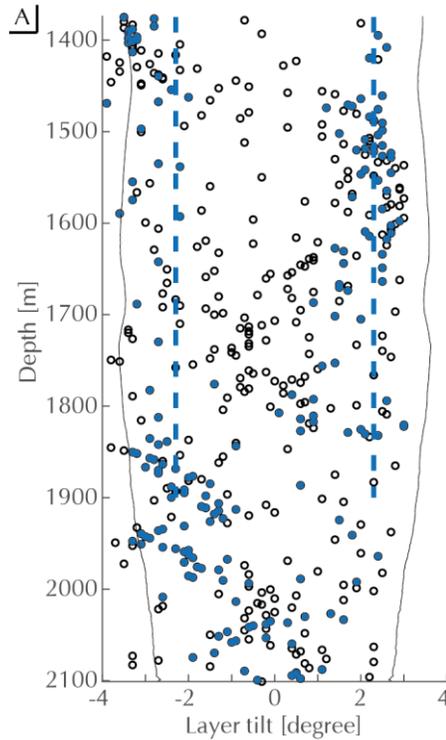

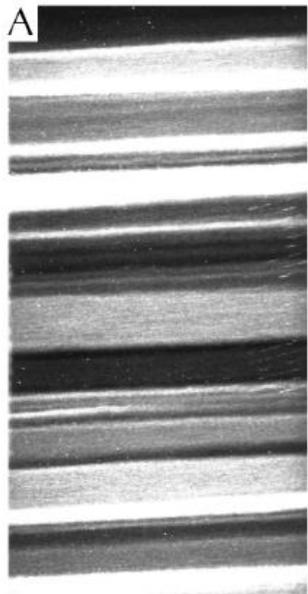

$$\delta_{(3,4)} = \varphi - 90 \pm (90 - \beta)$$

positive tilt
 $\delta_{(3,4)}$

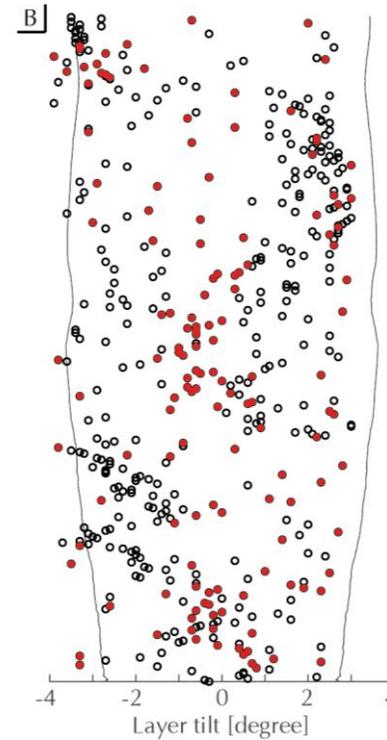

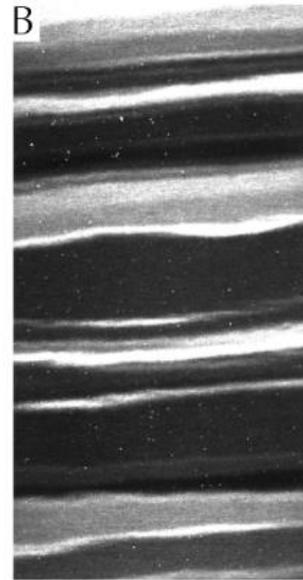

Geometrical reconstruction of the viewing direction of tilted layers, thus the ice core orientation.

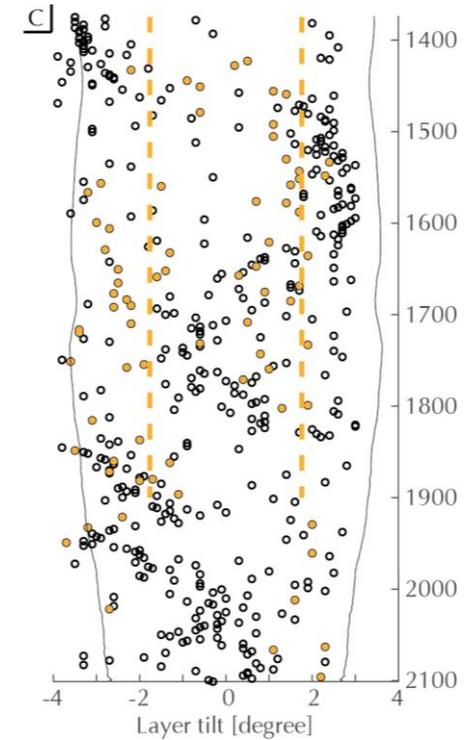

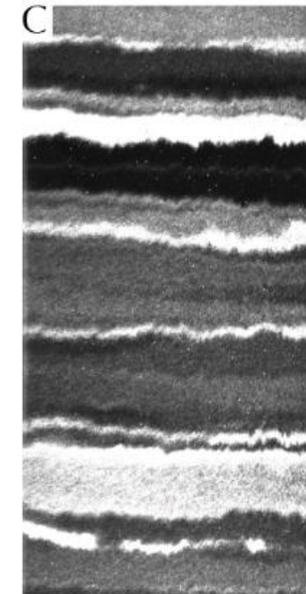

No features or flat layers

Undulations in layering

Crenulations (short upright folds)

Layers with features as in the image indicated as a colored point in the layer tilt overview. Dashed lines represent mean of positive and negative values.

Results

Input #1: borehole geometry
- azimuth direction (φ) and
- inclination (i)

Input #2:
visual stratigraphy image

Step 1:
determine tilt
of cloudy bands (α')

Step 2:
calculate β
[eq. 2]

is α' positive
or negative?

Step 3:
calculate δ
[eq. 3 and 4]

Step 4:
analyze deformation features:
- crenulations,
- folds with long wavelength,
- or no structures.
[e.g., right side]

Step 5:
determine better fit in respect
to ice flow direction
- positive: δ_1 or δ_2
- negative: δ_3 or δ_4

Result:
 δ represents the orientation of
a sample's cut plane

Examples:
 φ : 175.5°
 i : 3.6°

bag 2971
depth
1633.95m

$\alpha' = -1.3^\circ$

$\beta = 12^\circ$

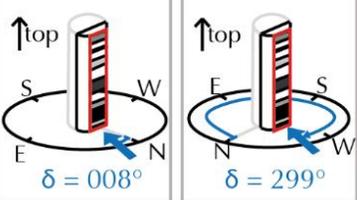

negative

$\delta_3 = 163^\circ$

$\delta_4 = 008^\circ$

crenulations

δ_4

bag 2972
depth
1634.05m

$\alpha' = 2.5^\circ$

$\beta = 56^\circ$

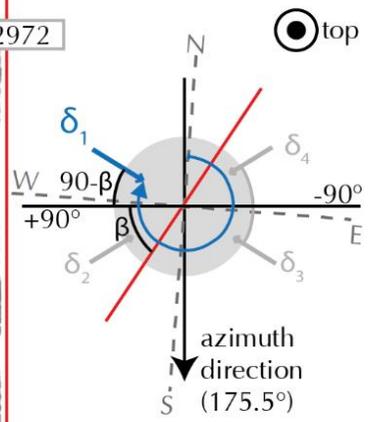

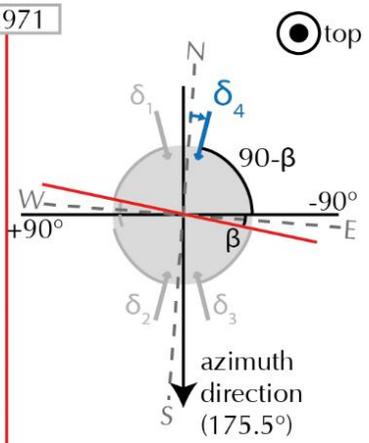

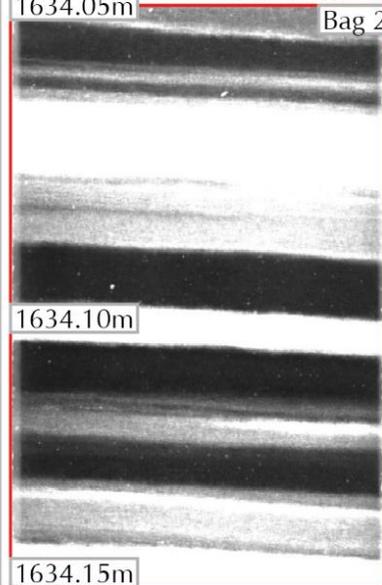

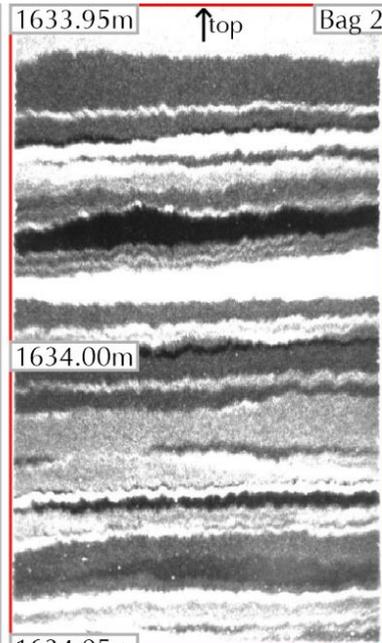

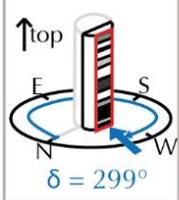

positive

$\delta_1 = 299^\circ$

$\delta_2 = 232^\circ$

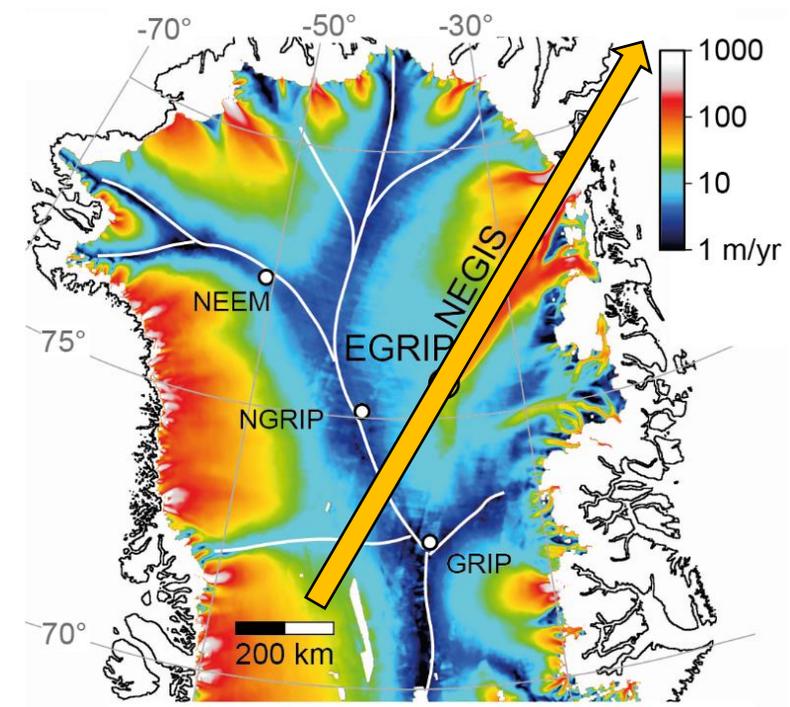

no structures

δ_1

000° = North, 090° = East,
180° = South, 270° = West

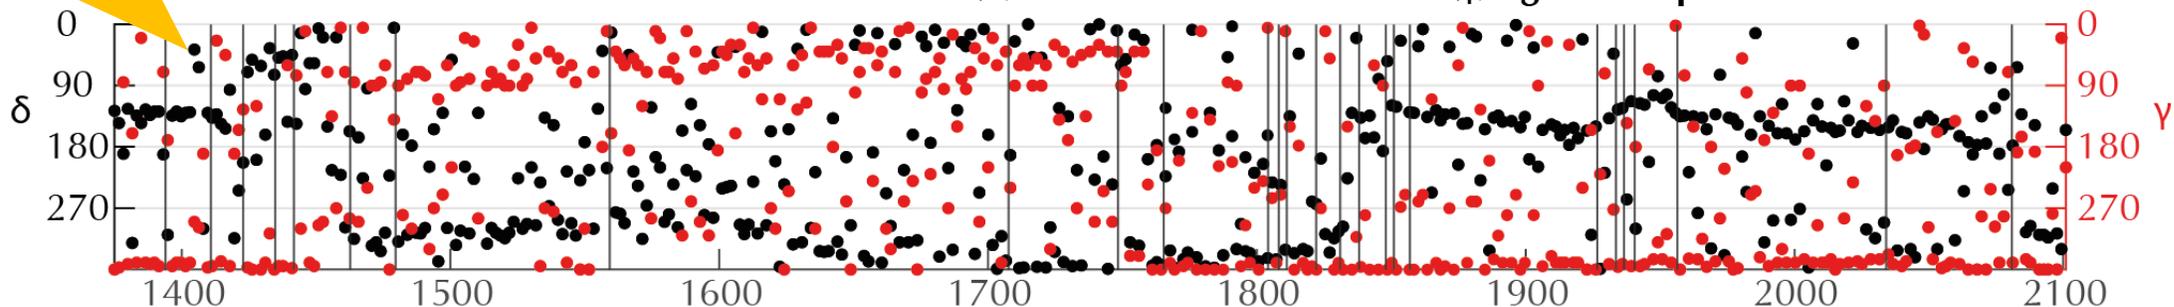

Flow chart for reconstructing ice core orientation (for details see paper). Ice flow direction, here NEGIS, is necessary for the reconstruction.

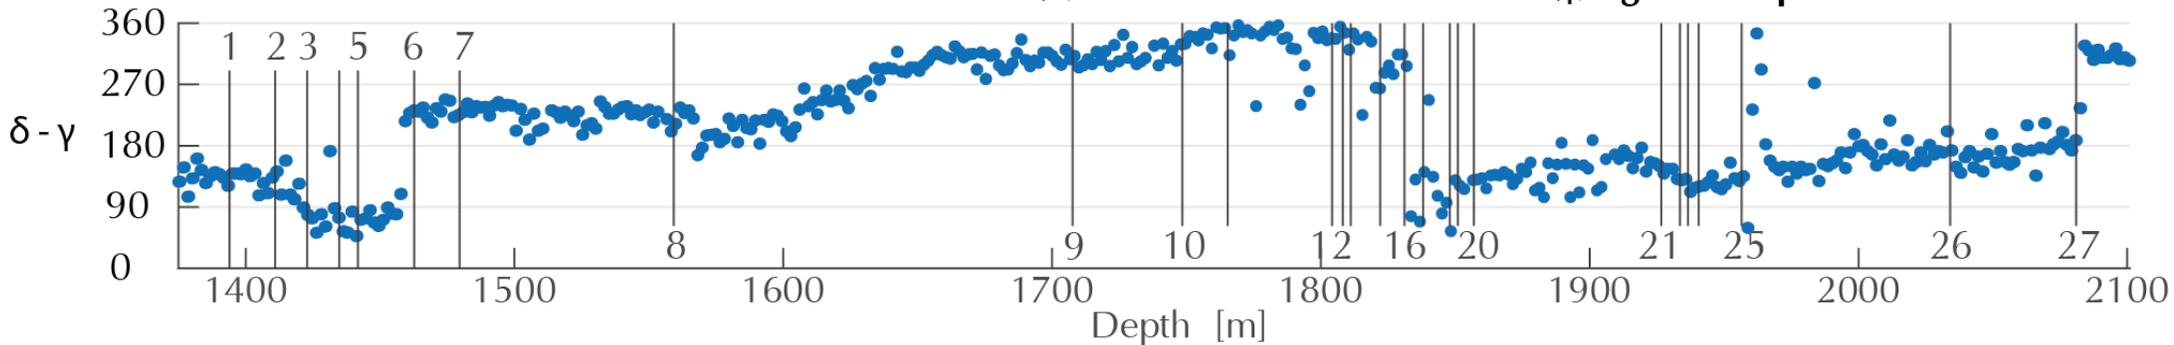

First time ever!

We are now able to quantify how well core break matching in the field works! For details, see paper.

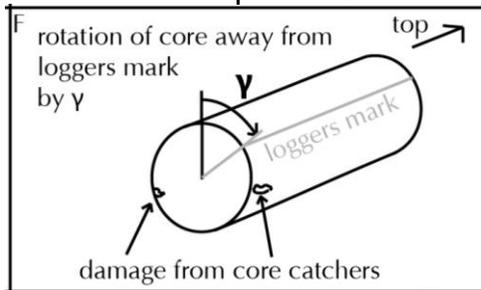

Absolute Orientation (δ) and Relative Orientation (γ) against Depth

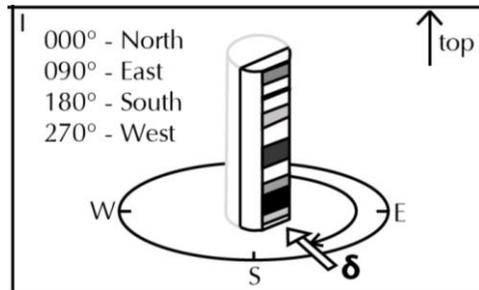

B Absolute Orientation (δ) minus Relative Orientation (γ) against Depth

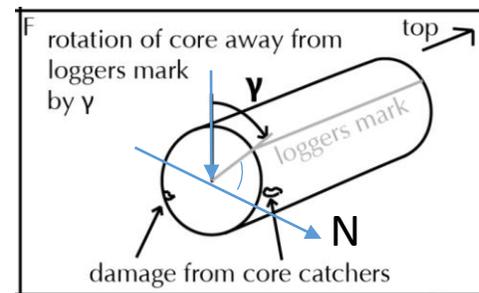

Explanation to terms in figure:

gamma:
relative
orientation

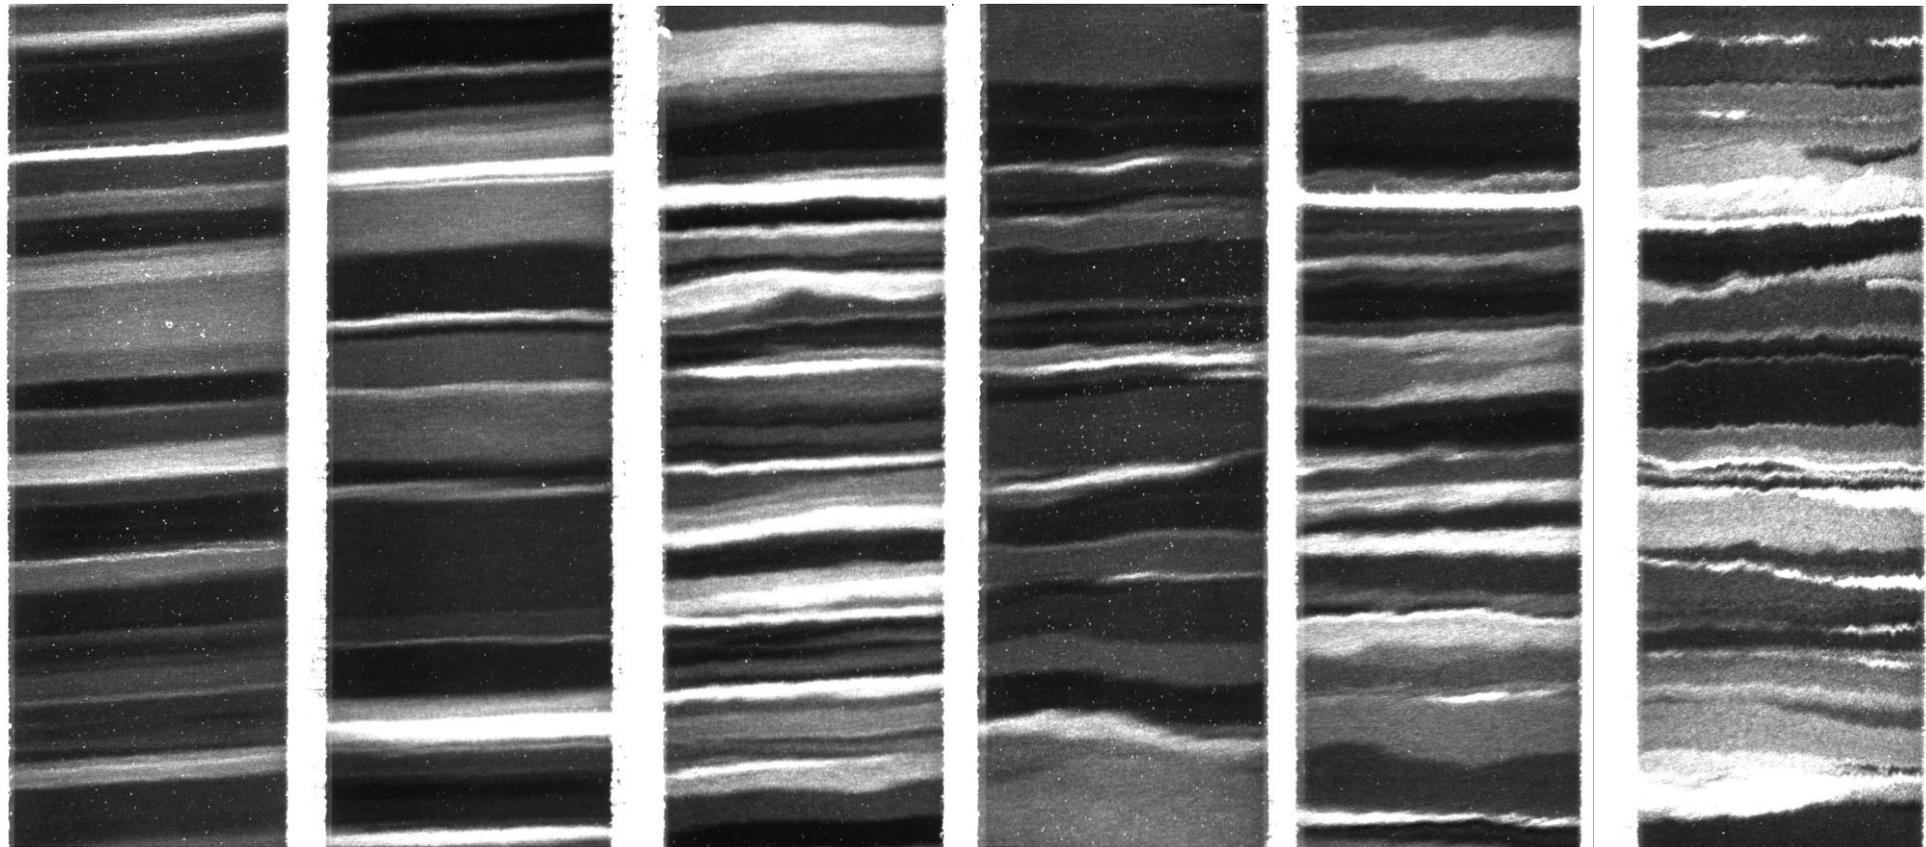

delta:
absolute
orientation

delta minus gamma:
angle of loggers
mark from North

- We have:
- oriented the glacial section of the EastGRIP ice core
 - shown that the structures below are an effect of core orientation, not change of deformation regime
 - shown that the method works using the fabric orientation and core break matching as references
 - paved the way for a detailed inspection of deformation structures in the ice core
